CUK-H06647-141-RP261

NATURE

A WEEKLY JOURNAL OF SCIENCE

"To the solid ground
Of nature trusts the Mind that builds for aye."—WORDSWORTH.

141

Volume 141

JANUARY 1, 1938, to JUNE 25, 1938

LONDON
MACMILLAN AND CO., LTD.
NEW YORK: THE MACMILLAN COMPANY

DATES AND PAGINATION OF WEEKLY ISSUES

Serial No.	Date of Issue	Pagination
3557	January 1	1–50
3558	,, 8	51–92
3559	,, 15	93–134
3560	,, 22	135–176
3561	,, 29	177–218
3562	February 5	219–260
3563	,, 12	261–302
3564	,, 19	303–344
3565	,, 26	345–386
3566	March 5	387–428
3567	,, 12	429–486
3568	,, 19	487–528
3569	,, 26	529–570
3570	April 2	571–620
3571	,, 9	621–662
3572	,, 16	663–704
3573	,, 23	705–762
3574	,, 30	763–804
3575	May 7	805–846
3576	,, 14	847–888
3577	,, 21	889–946
3578	,, 28	947–988
3579	June 4	989–1030
3580	,, 11	1031–1072

3582	,, 25	1115–1156

RP R271

INDEX

NAME INDEX

Aaron (Prof. R. I.), John Locke (*Review*), 1080
Abbie (A. A.), Classification of Marsupials, 42
Abel (Prof. J. J.), elected a foreign member of the Royal Society; work of, 963; [death], 1045
Abercrombie (Prof. P.), and others, Geography, the Basis of Planning, 170
Ackermann (A. S. E.), A Whale Story, 752
Adam (Prof. N. K.), Destruction of Sea-Birds by Oil, 324
Adams (W. E.), appointed lecturer in histology in Leeds University, 567
Addey (F.), Curious Effects of Globular Lightning, 722
Addicott (Alice Baldwin), Nest-Building of the Bush-Tit, 837
Adkins (E. W. O.), appointed a demonstrator in anatomy in Cambridge University, 843
Adkins (Prof. H.), Reactions of Hydrogen with Organic Compounds over Copper-Chromium Oxide and Nickel Catalysts (*Review*), 811
Adler (E.), and Prof. H. v. Euler, Lactoflavin in the Eyes of Fish, 790
Adrian (Prof. E. D.), Potential Changes in the Ears of Reptiles and Fish, 553
Ahier (G.), Some Dispersive Liquids, 944
Ahlmann (Prof. H. W.), Land of Ice and Fire (*Review*), 896
Aikawa (Dr. H.), Larval Characters of the Brachyura, 166
Aitken (A. C.), Studies in Practical Mathematics (3), 760
Aiyappan (A.), Nayadis of Malabar, 611
Aiyer (R. Gopala), and N. Kesava Panikkar, Swarming and Lunar Periodicity of a *Platynereis*, 560; [N. K. Panikkar and], Indian Brackish Water Fauna, 652
Alexander (Lt.-Col. R. D. T.), appointed a fellow of King's College, London, 426
Alexander (Dr. W. P.), Methods of Selection for Post-Primary Education, 110
Allen (Dr. E. J.), awarded the Agassiz medal for oceanography, 869; elected a fellow of University College, London, 426
Allen (Prof. F.), "Foundations of Terrestrial Life", 610
Allen (J. F.), and H. Jones, New Phenomena Connected with Heat Flow in Helium II, 243; and A. D. Misener, Flow of Liquid Helium II, 75
Allen (Prof. H. S.), Elementary Geometrical Optics (*Review*), 136
Allibone (Dr. T. E.), awarded the Coopers Hill War Memorial prize and medal, 282; D. B. Mackenzie and F. R. Perry, Effects of Impulse Voltages on Transformer Windings, 45
Allmand (Prof. A. J.), H. C. Craggs and G. V. V. Squire, Photochemical Union of Hydrogen and Chlorine, 253
Alston (Madeline), Wanderings of a Bird-Lover in Africa (*Review*), 100
Ammal (E. K. J.), Chromosome Numbers in Sugarcane × Bamboo Hybrids, 925
Ammon (Dr. R.), und Dr. W. Dirscherl, Fermente, Hormone, Vitamine: und die Beziehungen dieser Wirkstoffe zueinander (*Review*), 896
Amoureux (Mlle. Germaine), [A. Berthelot and], Formation of 3-Indol-Acetic Acid by the Action of Ultra-Violet Radiation on Tryptophane, 802
Andant (A.), Automatic Photography of the Raman Spectra of Liquid Mixtures, 1154
Anderson (Sir John), elected member of Parliament for the Scottish Universities, 408
Anderson (Prof. W. B.), Physics for Technical Students: Mechanics and Heat. Third edition. (*Review*), 224
Andersson-Kottö (I.), [Capt. C. Diver and], Dextrality of *Limnæa peregra*, 1020
Andrade (Prof. E. N. da C.), Prof. L. N. G. Filon, 357; and L. C. Tsien, Glide in Crystals, 85
Andrews (A. le Roy), A Criticism of Warnstorf's "Sphagnologia Universalis", 298
Andrews (E. W.), Snakes of Yucatan, 477
Andrieth (L. F.), [C. Sobutsky, R. W. Campbell and], Acid Catalysis in Liquid Ammonia (1), 385
Angus (R. H.), appointed lecturer in engineering in Cambridge University, 382
Anrep (Prof.), elected a corresponding member of the Vienna Biological Society, 783
Antoniadi (Dr. E. M.), Markings of the Third Satellite of Jupiter in Transit Across the Planet, 1106
Aoki (H.); [S. Kikuchi and], Wilson Chamber Photograph of the Neutro-Electric Effect, 328; Wilson Chamber Study of the Neutro-Electric Effect, 645
Appleton (Prof. E. V.), Dr. E. T. Farmer and J. A. Ratcliffe, Magnetic Double Refraction of Medium Radio Waves in the Ionosphere, 409
Armitage (Miss E.), A Binocular Illusion, 825
Armstrong (Dr. E. F.), Hydrocarbons (*Review*), 492
Armstrong (Miss Lilias), (Mrs. S. Boyanus), [obituary], 17
Arnold (R. N.), Impact Stresses in a Freely Supported Beam, 653
Arnot (Dr. F. L.), Cosmological Theory, 1142; and C. Beckett, Formation of Negative Ions at Surfaces, 1011
Arnulf (A.), [G. Déjardin and], Ultra-Violet Absorption Spectrum of Atmospheric Ozone, 91
Arup (Prof. D.), elected a member of the Royal Danish Academy, 783
Arutiunian (N.), [Prof. D. Kostoff and], Heterochromatic (Inert) Regions in the Chromosomes of *Crepis capillaris*, 51[illegible]
Ashley-Montagu (Prof. M. F.), Coming into being Among the Australian Aborigines: a Study of the Procreative Beliefs of the Native Tribes of Australia (*Review*), 263
Astbury (Dr. W. T.), and Florence O. Bell, X-Ray Study of Thymonucleic Acid, 747
Aston (Dr. F. W.), Packing Fractions of Bromine, Chromium, Nickel and Titanium, 1096
Astrup (Dr. T.), Schütz's Law and the Clotting of Blood, 1057
Atkins (Dr. W. R. G.), British Fisheries, Phosphate and the Solar Radiation Constant, 77
Aubrey (Rev. M. E.), elected a member of the Athenæum Club, 156
Auclair (M.), [A. Poirot and], Anode Rays of some Heavy Metals, especially Lead, 48
Augener (Dr. Hermann), [obituary article], 863
Auger (V.), The Molybdic Acid, H_4MoO_5, 944
Auld (Lt.-Col. S. J. M.), Petroleum Technology (*Review*), 573
Austen (Major E. E.), [death], 150; [obituary article], 358
Ayyangar (H. N. C.), Anatomy of the Ox, 84
d'Azambuja (L.), elected an associate of the Royal Astronomical Society, 683

Baashuus-Jessen (J.), Periodical Fluctuations in Game, 477
Bachelier (Prof. L.), Les lois des grands nombres du calcul des probabilités (*Review*), 55
Bačkovský (J. M.), Elimination of the Mosaic Crystal Imperfection Effect on the Width of X-Lines, 872
Baekeland (Prof. L. H.), awarded the Messel medal of the Society of Chemical Industry, 198
Bagchi (Dr. P. C.), The Second City of the Empire, 322
Bahl (K. N.), Osteology of *Varanus*, 124
Bailey (M. A.), appointed director of the National Institute of Agricultural Botany; work of, 1136
Baker (F.), and R. Martin, Disintegration of Cell-Wall Substances in the Gastro-Intestinal Tract of Herbivora, 877
Baker (G. P.), The Day Lily, 549
Baker (Prof. J. F.), [Prof. A. J. S. Pippard and], The Analysis of Engineering Structures (*Review*), 578
Baker (Dr. J. R.), conferment upon, by Oxford University, of the degree of D.Sc., 525
Ballard (L. A. T.), [Prof. H. H. Dixon and], A Simple Method of Showing Tension in the Sap of a Plant, 132
Banerjea (Dr. G. B.), and B. Pattnaik, Viscosity of Air and the Electronic Charge, 1010
Banerjee (Dr. S. S.), and B. N. Singh, Effect of Longitudinal Magnetic Field on the Refractive Index and Conductivity of Ionized Air, 511
Banks (N.), Neuropteroid Insects from Formosa, 42
Banks (Dr. T. E.), [Prof. F. L. Hopwood and], Canalization of Gamma Rays, 687
Barber (D. R.), [D. T. Edwards and], Objective Prism Observations of Nova Lacertæ (1936), 210
Barber (H. N.), Delayed Mitosis and Chromatid Fusion, 80
Barchewitz (P.), Complexity of the (CH) Bands of Benzene Derivatives, 702
Barclay (R. S.), and W. O. Kermack, Decline of the Birth-rate, 90
Barcroft (Sir Joseph), and D. H. Barron, Film Illustrating Movement of a Fœtus, 322
Bardet (J.), A. Tchakirian and Mlle. Raymonde Lagrange, Spectrographic Search for Traces of Elements in Sea Water, 660
Barendregt (F.), [Dr. M. J. L. Dols, Prof. B. C. P. Jansen, Prof. G. J. Sizoo and], Formation of Lipin Phosphorus in Normal and Rachitic Rats, with a Radioactive Phosphorus Isotope as an Indicator, 77
Barger (E.), Ethnographical Museums, 374
Barkar (Prof.), elected a corresponding member of the Vienna Biological Society, 783
Barkas (W. W.), and H. Q. Golder, Relation of Strength of Wood to Shrinkage, 874
Barker (H. P.), Centralized Control of Public Lighting, 934
Barnard (J. E.), elected president of the Royal Microscopical Society, 198
Barnard (Dr. K. H.), Western Indian Ocean as a Faunal Unit, 376
Barnes (Prof. R. M.), Motion and Time Study (*Review*), 460
Barnett (Dr. B.), appointed superintendent of the Rangoon Zoological Gardens, 509
Barr (Prof. A. S.), [Prof. C. V. Good, D. E. Scales and], The Methodology of Educational Research (*Review*), 494
Barrett (A. E.), and J. C. F. Tweed, Magnetic Recording in Broadcasting, 1005
Barrett (D. W.), The Clock of the Future, 507
Barrett (Sir James), The Australian Aborigines, 476
Barron (D. H.), [Sir Joseph Barcroft and], Film Illustrating Movement of a Fœtus, 322
Barrow (R. F.), and Dr. W. Jevons, Band Spectrum of Silicon Monosulphide, 833
Bartlett (Prof. F. C.), Co-operation of Social Groups, 519; Social Relations of Science, 729
Bartlett (Dr. M. S.), Methods of Estimating Mental Factors, 609
Barton-Wright (E. C.), General Plant Physiology (*Review*), 451
Bass (N. W.), W. R. Dillard and J. H. Hengst, Oil in Osage County, Oklahoma, U.S.A., 590
Bassière (M.), Structure of Sodium Isocyanate, 1154
Basu (Prof. M. N.), Blood Groups of the Noluas of Bengal, 649
Bate (Miss D. M. A.), [Miss D. A. E. Garrod and], The Stone Age of Mount Carmel: Excavations at the Wady el-Mughara, Vol. 1 (*Review*), 304
Batten (Miss Jean), awarded the gold medal of the International Aeronautical Federation, 241
Baumgardt (E.), Transparency of Solid Plates to Ultra-Sounds, 1154
Bawden (F. C.), and N. W. Pirie, A Plant Virus Preparation in a Fully Crystalline State, 513; Crystalline Preparations of Potato Virus *X*, 1105
Baxandall (D.), [obituary article], 402
Bay (Prof. Z.), Electron-Multiplier as an Electron-Counting Device, 284; 1011
Bayer (Prof. G.), elected a corresponding member of the Vienna Biological Society, 783
Beach (J. Y.), and D. P. Stevenson, Tetrahedral Angles in Butane Derivatives, 479
Beadnell (Surg. Rear-Adml. C. M.), Motor Traffic and Wild Life, 30; Scientific Tests of Telepathy, 878
Beaver (S. H.), Geography and Planning, 170; [Dr. L. Dudley Stamp and], with contributions by Sir Josiah Stamp and Dr. D. K. Smee, The British Isles: a Geographic and Economic Survey. Second edition (*Review*), 767
Beck (Prof. G.), Structure of Heavy Elementary Particles, 609; Magnitude of Nuclear Forces, 832
Becker (R.), Segregation of the Constituents of a Mixed Crystal, 981
Beckett (C.), [Dr. F. L. Arnot and], Formation of Negative Ions at Surfaces, 1011
de Beer (Dr. G. R.), appointed reader in embryology at University College, London, 985
Beevers (Dr. C. A.), awarded the Dewar research fellowship in Edinburgh University, 299
Belcher (D.), [D. A. MacInnes, T. Shedlovsky and], The *p*H Scale, 1106
Belgians (King of the), elected an honorary member of the Institution of Civil Engineers, 408
Bell (D. A.), Fluctuation Noise in Thermionic Valves, 833
Bell (Florence O.), [Dr. W. T. Astbury and], X-Ray Study of Thymonucleic Acid, 747
Bell (R. P.), presented with the Meldola medal of the Institute of Chemistry, 469
Bell (T. R. D.), and Lt.-Col. F. B. Scott, Moths. Vol. 5: Sphingidæ (The Fauna of British India, including Ceylon and Burma) (*Review*), 458
van Bemmelen (R. W.), Origins of Magmas, 653
Bemrose (Dr. H. H.), awarded the Murchison medal of the Geological Society of London, 154
Benedicks (Prof. C.), and P. Sederholm, Effects of Gas Ions on the Benedicks Effects in Mercury, 1097
Bennett (Prof. G. M.), appointed professor of chemistry in King's College, London; work of, 403, 426
Benson (C.), [death], 503
Benson (S. V.), The Observer's Book of British Birds (*Review*), 351
Bergel (Dr. F.), A. Jacob, A. R. Todd, and T. S. Work, Vitamin E: Structure of β-Tocopherol, 646
Berger (Prof. C. A.), Cytology of Metamorphosis in the Culicinæ, 834
Bergh (F.), Dr. O. M. Henriques and J. Schousboe, The Prague Sero Reactions for Cancer, 751
Bergius (Dr. F.), elected an honorary member of the Physical Association of Frankfort, 550
Bergmann (Dr. E.), and Prof. R. Samuel, Mechanism of the Primary Photodissociation Processes of Organic Molecules, 832; [C. Weizmann, Y. Hirshberg and], Photochemical Interaction between Ketones and Secondary Alcohols, 1012
Bergmann (Prof. L.), Schwingende Kristalle: und ihre Anwendung in der Hochfrequenz- und Ultraschalltechnik (*Review*), 535
Bergsøe (P.), Gilding of Copper among the Pre-Columbian Indians, 829
Berkner (L. V.), [H. G. Booker and], Constitution of the Ionosphere and the Lorentz Polarization Correction, 562

Bernal (Prof. J. D.), A Policy for Scientific Research for Britain, 320 ; Social Relations of Science, 736 ; Dr. I. Fankuchen and M. Perutz, An X-Ray Study of Chymotrypsin and Hæmoglobin, 523
Bernard (F.), Development of Compound Eyes, 1019
Bernard (R.), Sodium in the High Atmosphere, 788 ; Variations of Intensity of the Sodium *D* Line Present in the Spectrum of the Light of the Sky at Twilight, 1029 ; Possible Presence of Metastable Atoms of Nitrogen (^2P) in the High Atmosphere, 1140
Berry (E. W.), Succession of Fossil Floras in Patagonia, 50
Berthelot (A.), and Mlle. Germaine Amoureux, Formation of 3-Indol-Acetic Acid by the Action of Ultra-Violet Radiation on Tryptophane, 802
Berton (A.), [Mme. Zina Soubarew-Chatelain and], Ultra-Violet Absorption Spectra of the System MoO_3–NaOH in Dilute Solution, 802
Bertram (F. G. L.), [death], 587
Bertrand (G.), Unexpected Intervention of the Manure Industry in Reducing the Fertility of Soils, 526 ; and L. Silberstein, Distribution of Boron in the Organs of the White Lily, 886
Besredka (A.), Disappearance of the Vaccinating Power of Diphtheric Anatoxin in the Presence of Antidiphtheric Serum, 619
Best (Prof. C. H.), and Prof. N. B. Taylor, The Physiological Basis of Medical Practice (*Review*), 57
Beveridge (Sir William), Realistic Social Studies, 375
Bewley (W. F.), J. Harnett and P. H. Williams, Control of White Plaster Mould, 42
Bews (Dr. J. W.), Life as a Whole (*Review*), 853
Bhabha (Dr. H. J.), Production of Electron Showers by Cosmic Rays, 90 ; Nuclear Forces, Heavy Electrons and the β-Decay, 117
Bhatia (Dr. B. L.), Protozoa : Ciliophora (Fauna of British India, including Ceylon and Burma), (*Review*), 142
Bhatia (Dr. G. S.), Origin of Octoploid Wheat, 794
Bhatnagar (Prof. S. S.), Magnetism Relating to Chemistry, 296
Bickley (Dr. W. G.), and others, Relative Value of Pure and Applied Mathematics, 130
Bierry (H.), and B. Gouzon, Spectral Detection of the Œstrogenic Hormones in the Urine of a Pregnant Woman, 944
Bilham (E. G.), The Climate of the British Isles : being an Introductory Study of the Official Records, for Students and General Readers (*Review*), 851 ; The Spring Drought in the British Isles, 902
Biltz (W.), and P. Ehrlich, Silicon Monoxide, 881
Binnie (W. J. E.), elected president of the Institution of Civil Engineers, 935
Biquard (P.), Propagation of Ultra-Sounds in Liquids under Pressure, 944
Birch (A.), Structure of Origanene, 803
Birch (A. J.), Exudation of *Araucaria Bidwilli* ; the α-Phellandrene Fraction of Eucalyptus Oils, 761
Bird (C. L.), appointed lecturer in dyeing in Leeds University, 618
Birkinshaw (D. C.), [T. C. Macnamara and], London Television Service, 781 ; 1108
Biswas (Kalipada), conferment upon, of a doctorate by Edinburgh University, 216
Bizette (H.), and B. Tsai, Magnetic Susceptibility of Liquid Nitric Oxide, NO, 1154
Black (A. N.), appointed demonstrator and lecturer in engineering in Oxford University, 885
Black (M.), Relevance of Mathematical Philosophy to Mathematical Teaching, 130
Black (M.), appointed lecturer in geology in Cambridge University, 1028
Blackett (Prof. P. M. S.), The Social Background of the Rise of Science in the Seventeenth Century, 679 ; Social Relations of Science, 736 ; and others, Cosmic Rays, 1085
Blacktin (Dr. S. C.), awarded the Grey-Wilson memorial gold medal of the Institute of Patentees, 509
Blanc (Madeleine), and J. Weigle, Simultaneous Reflections and Deflected Action, 427
Blau (Marietta), and Hertha Wambacher, Photographic Investigation of Heavy Particles in Cosmic Rays, 385
Blüh (Dr. O.), Einfuhrung in die Physik (*Review*), 310
Bloch (Mlle. France), On Thioacids, 802
Blum (L.), Polarity of the Buffer Action in the Tissues of an Aquatic Plant (*Potamogeton densus*), 945
Blumlein (A. D.), The Transmitted Wave-form, 1108
Boell (E. J.), [Dr. J. Needham, Veronica Rogers and], Measurement of the Anærobic Glycolysis of the Regions of the Amphibian Gastrula by the Cartesian Diver Ultramicromanometer, 973
Bogert (Prof. M. T.), elected president of the International Union of Chemistry, 1044 ; awarded the Priestley gold medal of the American Chemical Society, 1095
Bohr (Prof. Niels), elected a *correspondant* of the Paris Academy of Sciences, 114 ; Nuclear Photo-Effects, 326 ; Quantum of Action and Atomic Nuclei, 981 ; Resonance in Nuclear Photo-Effects, 1096
Boissonas (C. G.), Calculation, for a Binary Mixture, of the Partial-Vapour Pressures starting with the Total Pressure, 427
Böker (Prof. H.), elected an honorary member of the Cuban Society of Natural History, 550
Bolton (E. R.), appointed a fellow of King's College, London, 426
Bonacina (L. C. W.), Landscape at the Royal Academy, 818 ; John Constable's Centenary : His Position as a Painter of Weather, 70
Bone (Prof. W. A.), [death], 1088
Bonhoure (A.), [A. Zmaczynski and], Boiling Point of Water as a Function of the Pressure, 217
Bonner (D.), [J. Bonner and], Ascorbic Acid and the Growth of Plant Embryos, 661
Bonner (J.), and D. Bonner, Ascorbic Acid and the Growth of Plant Embryos, 661
Booker (H. G.), and L. V. Berkner, Constitution of the Ionosphere and the Lorentz Polarization Correction, 562
Borer (O.), Reclamation of Tidal Lands, 443
Born (Prof. Max), Relativity and Quantum Theory, 327
Borocco (A.), Comparative Study of the Dissociation Pressures of Sodium and Potassium Hydrides and Deuterides, 91 ; Dissociation Pressure of Rubidium and Cæsium Hydrides and Deuterides, 1028
Borodin (Prof. N. A.), [death], 109
Bory (Dr. L.), awarded the prize of the Ducheume de Boulogne Academy, 156
Bosazza (V. L.), [Dr. G. Eloff and], Penetration of Ultra-Violet Rays through Chitin, 608
Bose (A.), [Prof. K. S. Krishnan and], Coupling between the Orbital and the Spin Angular Momenta of Paramagnetic Ions from Magnetic Measurements, 329
Bose (Dr. G.), Ambivalence, 381
Bose (Prof. S. R.), Effects of Radiation of Polypore Fungi, 936
Bosler (J.), Earth Currents and Magnetic Disturbances, 986
Boswell (Prof. P. G. H.), Social Relations of Science, 735 ; Prof. F. T. Brooks and Prof. Allan Ferguson, The Advancement of Science and Society, 557
Bothe (W.), [K. Schmeise and], A New Kind of Ultra-hard Cosmic Ray Shower, 982
Bottema (J. A.), [F. M. Jaeger, E. Rosenbohm and], Exact Measurement of the Specific Heats of Solid Metals at High Temperatures (29), 703
Bouchet (M.), A. Jullien, D. Vincent, and Mlle. Madeleine Vuillet, Diffusion of Acetylcholine starting with the Heart of *Helix pomatia*, 661
Boulenger (Dr. G. A.), [obituary article], 16
Boullé (A.), Calcium Trimetaphosphate, 702
Boutaric (A.), Application of the Dilatometric Method to the Study of Colloidal Gels, 802
Bovien (R.), Association between Nematodes and Insects, 758
Bowden (Dr. F. P.), and L. Leben, Nature of Sliding and the Analysis of Friction, 691
Bowden (Dr. S. T.), A Modified Phase Rule Equation, 331
Bowen (W. H.), Appendicitis : a Clinical Study (*Review*), 462

Boycott (Prof. A. E.), conferment upon, of the title of professor emeritus of pathology, 426 ; [death], 929
Bozorth (R. M.), Higher Magnetic Permeabilities, 796
Bracher (Dr. R.), Ecology in Town and Classroom (*Review*), 392
Bradford (Dr. S. C.), An Index to Scientific and Technical Constants (*Review*), 808
Bradley (G. W. J.), By-product Coking, 865
Bragg (Sir William), awarded the Institute of Metals medal, 469 ; "Clay", 649 ; Social Relations of Science, 725
Bragg (Prof. W. L.), appointed Cavendish professor of experimental physics in Cambridge University ; work of, 403 ; elected a professorial fellow of Trinity College, Cambridge, 567 ; elected professor of natural philosophy in the Royal Institution, 935 ; and H. Lipson, Structure of Metals, 367
Brahmachari (Sir U.), Kala-azar and Malaria, 379
Branson (H.), [H. Kersten and], Effects of Soft X-Rays upon Chætopods, 554
Braunholtz (H. J.), Ancient Pottery from Peru, 1104 ; [R. W. Feacham and], Note on Exhibition of Antiquities from British Honduras, 932
Brdička (R.), Application of the Polarographic Protein Reaction for Cancer Diagnosis, 619
Brenchley (Dr. Winifred E.), and Dr. D. J. Watson, Heart-rot of Sugar Beet, 167
Breuil (Abbé H.), Palæolithic Age in Palestine (*Review*), 304 ; 'Bone Age' Man, 651
Brickwedde (Dr. F. G.), [Dr. F. B. Silsbee, R. B. Scott and], Some Experiments at Radio Frequencies on Supraconductors, 75
Briejèr (C. J.), Control of Insects by Methallyl Chloride, 1099
Brightman (R.), Social Values of Science (*Review*), 99
Briner (E.), C. El-Djabri and H. Paillard, Ozonation of Some Hydrocarbons (Hexane, Heptane, and Various Octanes), 485
Briscoe (Prof. H. V. A.), awarded the Consolidated Gold Fields of South Africa, Ltd., gold medal, 783
Broadbent (H. F.), New Flight Record, 783
Brode (R. B.), and M. A. Starr, Production of Cosmic Ray Showers, 561
Brons (F.), and Dr. C. J. Gorter, Stimulation of Paramagnetic Absorption by a Constant Field, 369
Brontman (L.), edited by O. J. Schmidt, On the Top of the World : the Soviet Expedition to the North Pole, 1937 (*Review*), 995
Brooks (Prof. F. T.), [Prof. P. G. H. Boswell, Prof. Allan Ferguson and], The Advancement of Science and Society, 557
Brooks (H. E.), [R. A. H. Gray and], Control of the Red Spider Mite, 519
Broom (Dr. R.), More Discoveries of *Australopithecus*, 828
Brown (F. A.), and D. H. Thompson, Choice of Background in Fishes, 166
Brown (F. G.), Inclinations to Line of Sight of Non-Galactic Nebulæ, 796
Brown (Dr. G. Burniston), Organ Pipes and Edge Tones, 11
Brown (H. B.), and A. J. Bryant, Engineering Science. Vol. 1 (*Review*), 224
Brown (Prof. R. N. Rudmose), The Soviet Polar Station (*Review*), 995
Brown (Dr. W.), Psychology of International Relations, 152
Browne (C. O.), Vision Input Equipment, 1108
Browne (E. T.), bequests for research in marine biology, 636
Browning (Dr. H. M.), and L. Starbuck, Practical Physics for Inter. B.Sc. Students (*Review*), 136
Brun (P.), Study of the Properties of Metallic Ions in Alcohol, 300
Brunel (A.), Degradation of Substances of Puric Origin in the Lamellibranch Molluscs, 886
Brunschwig (P.), [F. Chodat and], New Researches on Cresol Blue (Tyrosinase, Paracresol, Amino Acids), 845
Brunt (Prof. D.), Gliding and Soaring Flight, 442 ; 712 ; Climatology of the British Isles (*Review*), 851
Bryant (A. J.), [H. B. Brown and], Engineering Science. Vol. 1 (*Review*), 224
Buckingham (R. A.), [H. S. W. Massey and], Long-range Forces between Hydrogen Molecules, 1112
Buckmaster (Prof. G. A.), [death], 67 ; [obituary article], 190
Buller (Prof. A. H. R.), Fusions between Flexuous Hyphæ and Pycnidiospores in *Puccinia graminis*, 33
Bunyard (E. A.), History of the Peach, 838

Zwicky (F.), and others, The New Super-Novæ, 481

TITLE INDEX

α-Copper-Zinc Alloys, A New Type of Structure in the, Prof. F. N. Rhines and A. M. Montgomery, 413
α-Leonis, Apparent Diameter of the Star, P. Rossier, 426
α-Particles, Artificial Radioactivity produced by, L. N. Ridenour and W. J. Henderson, 126
α-Tocopherol (Vitamin E), Synthesis of, Prof P. Karrer, H. Fritzsche, B. H. Ringier and H. Salomon, 1057
α Ursæ Majoris, System of, Dr. H. Spencer Jones and H. H. Furner, 377
Aberdeen University: resignation of Prof. A. Low, 504; conferment of honorary doctorates on Dr. E. J. Butler and Dr. G. Dahlberg, 860
Acenaphthene, Irregular Mitosis and Meiosis Induced by, Prof. D. Kostoff, 1144
Acanthodriline Earthworms of South Africa, A Monograph of the, Dr. Grace Evelyn Pickford (*Review*), 452
Acetyl Chloride as a Chlorination Agent in Inorganic Chemistry, A. Chretien and G. Oechsel, 567
Acetylcholine: Mechanism of the Biological Synthesis of, Dr. E. and Mrs. Ellen Stedman, 39; Dr. P. J. G. Mann, Dr. M. Tennenbaum and Dr. J. H. Quastel, 374
Aconitum heterophyllum, Atisine of, and the Anthorine of *Aconitum anthora*, A. Goris, 91
Actonian Prize, The [1838], 1027
Adaptation Energy, Prof. H. Selye, 926
Adelaide University, Dr. J. Davidson appointed professor of entomology in, 382
Adenosine, Inactivation of, by Blood, Drury, Lutwak-Mann and Solandt, 336
Administration, Science in, 219
Adrenal Cortex Differences in Male and Female Mice, Dr. Ruth Deanesly, 79; Dr. W. Cramer; Dr. Ruth Deanesly, 286
Adsorption of Constituents of a Solid Phase on the Surface, Dr. S. Dobinski, 81; Potentials, S. R. Craxford, O. Gatty and Lord Rothschild, 1098
Æolid Molluscs, Structure and Function of the Alimentary Canal of, with a Discussion on their Nematocysts, A. Graham, 343
Aeronautical Research in Australia, 940
Aeroplane Flight Records, New, Flying-Officer A. E. Clouston and V. Ricketts, 601
Africa: West Tropical, The Useful Plants of, Dr. J. M. Dalziel (*Review*), 54; Tropical, Soil Conservation in, Dr. L. Dudley Stamp, 268; Disappearing Fauna of, 443; The Man-made Desert in, Erosion and Drought, Prof. E. P. Stebbing, 639; Fauna and Flora of, International Conference for the Protection of the, 1024; and Melanesia in Transition, Prof. R. Thurnwald, 1061
Agaricaceæ of Hokkaido, Japan, S. Imai, 1105
Agricultural: Experimentation in the United States, 1607–1925, History of, A. C. True, 508; Research Council, Sir Thomas H. Middleton appointed chairman of the, 1002; Policy for Peace and War (*Review*), 1036; Research, Farmer's Guide to, 1937, 1051
Agriculture, Application of Science to, Sir John Russell, 799
Agriolimax agrestis L., the Grey Field Slug, Life-history and development of, R. Carrick, 985
Ainu Marriage Ceremonial, Dr. N. G. Munro, 651
Air: Viscosity of, P. J. Rigden, 82, Viscosity of, and the Electronic Charge, Dr. G. B. Banerjea and B. Pattanaik, 1016; Almanac, The (*Review*), 139; Navigation, Tables for (*Review*), 139; -Raids on Barcelona, 546
Aircraft: Ice Accretion on, Sir George C. Simpson, 167; Automatic Control for, 364; Composite, Official Tests of, 405
Al I Terms, Revision of, Dr. R. Schmid, L. Gero, K. Lörinczi and G. Neu, 1017
Alaska to Asia, Stepping Stones from, Isobel Wylie Hutchison (*Review*), 465
Albino Mouse, Reproduction in the, H. Merton (1), 343
Alchemy: in Scotland, Prof. J. Read, 405; under James IV of Scotland, Prof. J. Read, 940
Alcohols, Secondary, Ketones and, Photochemical Interaction between, C. Weizmann, Y. Hirshberg and Dr. E. Bergmann, 1012
Alexandria, Hydrobiology and Fisheries Laboratory, Hussein Faouzi, 1107
Algæ, Aerial and Soil, Investigation of, A. Quispel, 1155
d'Algèbre et de géométrie, Leçons, à l'usage des étudiants des Facultés des Sciences, Prof. R. Garnier. Tome 3 (*Review*), 769
Algeria, Cancer in, Campaign against, 868
Algol, Minima of, Spectrophotometric Study of the, Tcheng Mao-Lin, 216
Aliphatic Diazo Compounds, The, Prof. J. Kenner (Bedson lecture), 424
Alkalis, Specific Heat of the, L. G. Carpenter, T. F. Harle and C. J. Steward, 1015
Alloys of Magnesium, 45
Aluminium: Electrolytic Polishing of, P. Jacquet, 217; Ultra-pure, Reflecting power of, Dr. P. Jacquet and Dr. L. Capdecomme, 752, Transmutation of, Fine Structure of the Yield-Curve of the, A. Szalay, 972
Ambivalence, Dr. G. Bose, 381
Amaryllis Culture, William Herbert and, 884
America Revisited, Dr. G. W. C. Kaye, 495
American: Chemical Society, gift to, by Prof. J. P. Kendall, 32; award of the Priestley gold medal to Prof. M. T. Bogert, 1095; Institute of the City of New York, award of the gold medal of the, to Dr. W. Crocker, 277; and of the Institute fellowship to W. Kaempffert and Dr. R. L. Ditmars, 278; Museum of Natural History, Dr. L. J. Spencer elected a corresponding member cf the, 641; Society of Plant Physiologists, Prof. H. H. Dixon elected an honorary corresponding member of the, 641; School Buildings, 868; College of Physicians, award of the John Phillips memorial medal to Prof. H. Goldblatt, 1008
Amino Acids from Atmospheric Nitrogen, Biological Synthesis of, Prof. A I. Virtanen and T. Laine, 748
Ammonia, Liquid, Acid Catalysis in, C. Sobutsky, L. F. Andrieth and R. W. Campbell, 385
Amphibian Mesectoderm, M. Ishikawa, 754
Anaphylactic Sensitivity produced by a Chemical Substance, Prof. H. E. Fierz-David and Werner-Jadassohn, 517
Anatomical Terms, Improvement and Unification of, International Committee for the, Prof. H. Stieve nominated president of the, 869
Anatomy, Regional, Short Manual of, J. A. Keen (*Review*), 462
Ancient: Man in Devon, J Reid Moir, 335; World: The Mind of the, a Consideration of Pliny's Natural History, H. N. Wethered (*Review*), 708; Monuments: of Great Britain: List of Monuments to December 31, 1937, 848; in Britain, Protection of, 848
Andes, Northern, Archaic Culture of the, A. Métraux and H. Lehmann, 41
Anhydrite, Gypsum and, A. E. Hill, 85
Animal: Foods, Analysis of (*Review*), 225; Nutrition: Prof L. A. Maynard (*Review*), 264; The Newer Outlook on (*Review*), 264; Collecting, J. E. Hamilton (*Review*), 709; Treasure, I. T. Sanderson (*Review*), 709; Population, Bureau of, Report for 1936–37, 822
Animals: for Show and Pleasure in Ancient Rome, G. Jennison (*Review*), 390; in Ancient Rome, F. S. Marvin (*Review*), 390
Anode Rays of some Heavy Metals, especially Lead, A. Poirot and M. Auclair, 48

Anærobic Glycolysis of the Regions of the Amphibian Gastrula, Measurement of the, by the Cartesian Diver Ultramicromanometer, Dr. J. Needham, E. J. Boell and Veronica Rogers, 973
Anol, Action of, and its Derivatives on the Nipple of the Guinea Pig, Prof. H. E. Fierz, Dr. W. Jadassohn, E. Uehlinger and R. Monnier, 974
Ant-tree of Guiana [1838], 617
Antarctic Crinoids, D. D. John, 209; Macroplankton, Seasonal Circulation of the, Dr. N. A. Mackintosh, 1026; Plankton, 1026
Anthracite Coal for Iron Smelting, [1838], 484
Anthropology as an Imperial Study, Prof. J. H. Hutton, 699
Anti-hormonal Immunization and Specificity, E. Guyenot and Kitty Ponse, 845
Antirrhinum Rust, D. E. Green, 294
Apatite, Nepheline, and Rare-Earth Mining in the Kola Peninsula, Dr. G. W. Tyrrell, 354
Apia Observatory, Western Samoa, resignation of J. Wadsworth of the directorship of, 1008
Apophyllite, Morphology of, J. D. H. Donnay, 49
Appendicitis: a Clinical Study, W. H. Bowen (*Review*), 462
Apple Scab Fungus, R. McKay, 795
Aquarids, Rich Display of the, M. A. R. Khan, 968
Aquarist and Pond-Keeper, 868
Aquatic: Organisms, Density of Living, A. G. Lowndes, 289; Diptera, Prof. O. A. Johannsen, 1146; Diptera, Larvæ and Pupæ of, Prof. O. A. Johannsen, 335
Araucaria Bidwilli, Exudation of, A. J. Birch, 761
Archæological: Discovery at Sakkara, Egypt, W. Emery, 112; British, Investigation in France, 195; Discovery in Britain, 1933–38, 633; Studies in Ireland, 1031
Archæology: in South Africa, Dr. D. Randall-MacIver (*Review*), 222; Irish, New Aspects and Problems in, Dr. A. Mahr, 1041
Arctic America, Mounds of, A. E. Porsild, 252
Argon: Neon and, in the Earth's Crust, Lord Rayleigh, 410; Nitrogen and, in the Earth's Crust, Lord Rayleigh, 970
Aristotle's Physics: a Revised Text, with Introduction and Commentary, W. D. Ross (*Review*), 184
Arnott's Stoves, Dr. Neil, [1838], 215
Arrows, Axial Spin of, Dr. H. E. Durham, 290
Asbestos, G. E. Howling. Second edition, 1135
Ascorbic Acid: Treatment with, of the Plasma of a Fowl Affected by Erythroblastosis, Dr. E Morelli and Dr. A. Vorcellone, 202; Role of Manganese in the Biological Synthesis of, M. N. Rudra, 203; and the Growth of Plant Embryos, J. Bonner and D. Bonner, 661
Ascorbigen in Plant and Animal Tissues, Prof. B C. Guha and P. N. Sen-Gupta, 974
Ashmolean Society, [1838], 1068
Aspergillus niger, *Aspergillus repens* and *Penicillium glaucum* in the Presence of Carbon, Cultures of the Lower Plants such as, Mme. Yvonne Jérome-Lévy, 987
Assyrian Chemistry of the Seventh Century B.C., Dr. R. Campbell Thompson, 612
Astacura and Palinura of the John Murray Expedition, 1933–34, Dr. M. Ramadan, 1146
Asthenosphere, Viscosity of the, Significance of Gravity Anomalies in Relation to the, N. A. Haskell, 411
Astronomical: Micrometer, A New Double Image, P. Muller, 90; Instruments, Levelling the Axes of, Application of the Inverted Elastic Pendulum to, P. Lejay, 660; Thought in Renaissance England: a Study of the English Scientific Writings from 1500 to 1645, F. R. Johnson (*Review*), 665; Exhibits, 1049
Astronomer Royal for Scotland, W. M. H. Greaves appointed, 236
Astronomy: Ancient, Studies in, 29; Prof. W. M. Smart (*Review*), 457; for the Layman, F. Reh (*Review*), 494
Astrophysical Problems, Kramer's Absorption Law in, T. L. Page, 1137
Asymmetric-Sideband Broadcasting, P. P. Eckersley, 524
Asymptotic Expansions, Certain, and Corresponding Generalized Hypergeometric Functions, Induction Proofs of the Relations between, Dr. T. M. Macrobert, 90
Athenæum Club: Neville Chamberlain, Rev. M. E. Aubrey and Viscount Nuffield elected members of the, 156; Hon Sir Evan Charteris, Sir Francis Lewis Castle Floud and Sir John Ledingham elected members of the, 509
Athens University, conferment of an honorary doctorate on Sir James Frazer, 968
Atlantic: Steam Ferry, centenary of the, 540; Flight and its Bearings on Meteorology, F. Entwistle (Symons memorial lecture), 546
Atmosphere: Photochemistry of the, W. Groth and H. Suess, 479; High, Sodium in the, Prof. J. Cabannes, Prof. J. Dufay and J Gauzit, 1054
Atmospheric: Pressure, Earthquakes and, R. C. Hayes, 167; Carbon Dioxide, Effects of Variations in, G. S. Callendar, 561; Pollution in Dublin, A. G. G. Leonard, 1069
Atomic: Molecular and, Weights, Determination of, 152; Nuclei, Structure of, and Nuclear Transformations, Prof. G. Gamow (Second edition of "Constitution of Atomic Nuclei and Radioactivity") (*Review*), 391; Clock in Motion, Rate of an, Dr. H. E. Ives, 551
Atomically Stratified Medium, Double Refraction of an, J. Weigle, 427
ε-Auriga: –a Super-giant Star, Dr. O. Struve, 154; Interpretation of, Kuiper, Struve and Stromgren, 337
Aurora: of January 25–26: 192; 232; Cosmic Rays and the, Prof. V. F. Hess, R. Steinmaurer and A. Demmelmair, 686; The, Prof. S. Chapman, 695; Australis on January 22, J. Gregory, 722; of January 25: Spectrum of the, J. Dufay and J. Gauzit, 761; Photographic Measurements of the, Prof. C. Stormer, 955; of January 25, 1938, H. Tollner, 1113
Auroral Spectrum, Altitude Effects in the Red Part of the, and the Two Types of Red Auroras, Prof. L Végard, 200
Aurorous and Magnetic Storms, Recent Solar Eruptions, A. J. Higgs and R. G. Giovanelli, 746
Australia: Policy and the Aborigines in, Dr. D. F. F. Thomson, 68; Fisheries Research in, 600; Approval for a Reference Standards Laboratory, 640; Aeronautical Research in, 940; Inland, Nutritional Surveys of, Problems of Child Nutrition, Dr. F. W. Clements, 1023
Australian: Cancer Conference, report of the eighth, 20; Timbers, Seasoning of, W. L. Greenhill and A. J. Thomas, 72; *Science Abstracts*, 113; Aborigines: Coming into Being among the, A Study of the Procreative Beliefs of the Native Tribes of Australia, Prof. M. F. Ashley-Montagu (*Review*), 263; Procreative Beliefs of the, Prof. A. R. Radcliffe-Brown (*Review*), 263; The, Sir James Barrett, 476; Pines, Disease of, W. V. Ludbrook, 652; Aborigines, Decorative Art of the, Dr. D. S Davidson, 1104
Australopithecus, More Discoveries of, Dr. R. Broom, 828
Austria: Medical Men in, 549; Dismissals of Scientists in, Margaret Gardiner, 1101
Autonomic Neuro-Effector Systems, Prof. W. B. Cannon and Prof. A. Rosenblueth (*Review*), 266
Autres mondes, Sur les, L. Rudaux (*Review*), 1080
Auxin Extraction, Simplified Method for, J. van Overbeek, 569
Aviation, Civil, in Great Britain, 571
A Vitamins and Carotenoids, P. Meunier and Y. Raoul, 1029
Axial Spin and Weapons of the Ancients, M. J. B. Davy, 123
Azeotropic Concentrations, Determination of, by the Twin Pycnometers Method, Prof. M. Wojciechowski, 691
Azotobacter of the Soil, Attack of the Benzene Nuclei and the Utilization for Food of Phenol by the, G. Guittonneau and R. Chevalier, 886

β-Decay, Nuclear Forces, Heavy Electrons and the, Dr. H. J. Bhabha, 117
β-Phase, Law of the Precipitation of the, by Reheating an Aluminium-Magnesium Alloy Containing 12·7 per cent of Magnesium, R. Michaud, 300
β-Tocopherol, Structure of, Vitamin E: Dr. F. Bergel, A. Jacob, Dr. A. R. Todd and T. S. Work; Dr. J. F. Danielli, 646
Babylonian: Mathematics (*Review*), 5; Algebra, S. Gandz, 43
Bacteriology, Fundamentals of, Dr. M. Frobisher, Jr. (*Review*), 457
Banks's House, Marble Mantelpieces from, 441
Bantu-Speaking Tribes of South Africa: The, an Ethnographical Survey, Edited by Prof. I. Schapera (*Review*), 669
Barrier-Layer Cells, Response of, to X-Rays of Long Wave-length, Dr. A. E. Sandstrom, 873
Basin Cultivation in the United States, L. Olson, 858
Basle University, conferment of honorary doctorates on Prof. P. Karrer and Prof. L. Ruzicka, 114
Bath, Hot Springs of, Rare Gases from the, Prof. M. W. Travers, 85
Bathychordæus, The Genus, W. Garstang, 42
Battersea Polytechnic, Report for 1936–37, 508
Be(α, n), Stimulation Function of the Nuclear Reaction, J. Crussard and S. Gorodetzky, 132
Bedbug: Use of Sulphur Dioxide against the, H. C. Gough, 164; A. W. McKenny Hughes. Fourth edition, 293
Belfast: Queen's University, A. H. Naylor appointed professor of engineering, 985; -Stranraer Telephone Cable, 1050
Belgian Congo, National Parks of the, 32
Belief and Action: an Everyday Philosophy, Viscount Samuel (*Review*), 56
Benedicks Effects in Mercury, Effects of Gas Ions on the, Prof. C. Benedicks and P. Sederholm, 1097
Bentinck Island, Queensland, Natives of, E. K. Patterson, 560
Benzene: Derivatives, Complexity of the (CH—) Bands of, P. Barchewitz, 702; Structure of, Prof. C. K. Ingold (Bakerian lecture), 1150
Berlin Microbiological Society, Prof. H. Zeiss elected president of the, 509
Bidder, Organ of, in the Male Castrated Toad, Action of Pre-pituitary Extracts on the Development of the, R. Dovaz, 945
Binary: Systems, Single Spectrum, Masses in, Prof. H. C. Plummer, 420; Mixture, The Calculation for a, of the Partial Vapour Pressures Starting with the Total Pressure, C. G. Boissonnas, 427; Mixtures, Viscosity of, A. J. A. van der Wyk, 427; Systems of the Solid Solution Type, Composition of Minima in, M. Hara, 873
Binocular Illusion, A, Prof. H. H. Dixon, 792; Miss E. Armitage, 825; Dr. R. S. Creed, 977; Dr. R. W. Gurney, 1060
Biochemical Feast, A, Prof. A. Wormall (*Review*), 349
Biochemistry: in India, 31; Perspectives in: Prof. J. Marrack, 109; Edited by Dr. J. Needham and D. E. Green (*Review*), 349
Bioclimatics: A Science of Life and Climatic Relations, Dr. A. D. Hopkins, 1146
Biological: Control of an Insect in Fiji: an Account of the Coconut Leaf-mining Beetle and its Parasitic Complex, Dr. T. H. C. Taylor (*Review*), 179; Positivism, Prof. J. B. S. Haldane (*Review*), 265
Biologie: Mathematische Methoden der, insbesondere der Vererbungslehre und der Rassenforschung, Dr. F. Ringleb (*Review*), 57
Biology: General, A Textbook of, Prof. E. Grace White. Second edition (*Review*), 100; The Axiomatic Method in, Dr. J. H. Woodger. With appendices by A. Tarski and W. F. Floyd (*Review*), 265
Biot's Experiments on Tartaric Acid, [1838], 258
Bird: -Lover in Africa, Wanderings of a, Madeline Alston (*Review*), 100; New to Great Britain, H. F. Witherby, 782; -Ringing, Recent Advances in, 1133
Birds: Experiments on Homing in, Prof. K. Wodzicki, W. Puchalski and H. Liche, 35; Nests, Edible, in the Philippines, C. G. Manuel, 20; British, The Observer's Book of, S. V. Benson (*Review*), 351; Migrant, Habits of, in Winter Quarters, R. E. Moreau, 418; Wild, More Songs of, E. M. Nicholson and L. Koch (*Review*), 458; British: A Handbook of, H. F. Witherby, Rev. F. C. R. Jourdain, N. F. Ticehurst and B. W. Tucker. Vol. 1 (*Review*), 1037; Seton Gordon (*Review*), 1037
Birmingham University: Physics Department of, 743; Report of, 780
Birthcoat Kemp Follicles, Succession in, Dr. F. W. Dry, 921
Birthrate, Decline of the, R. S. Barclay and W. O. Kermack, 90
Black Musketeers: The, The Work and Adventures of a Scientist on a South Sea Island at War and at Peace, A. J. Marshall (*Review*), 465
Blood: Group Inheritance, J. Ff. Edwards and Dr. I. M. H. Etherington, 246; Clot, Optimum Temperature of Formation of a, R. M. Savage and W. P. Chambers, 287; Group Inheritance, J. C. Thomas, 415; Cultures and their Significance, Hildred M. Butler (*Review*), 461; and Soil, 621; Vessels, Size of, Influence of Circulation on, A. F. W. Hughes, 651; Groups and Pigmentation, M. A. MacConaill, 923; Clotting of, Schutz's Law and the, Dr. T. Astrup, 1057; Sedimentation, Stratified, Isolation of Immature Red Cells, J. G. Stephens, 1058; Pressure, Ascorbic Acid, Acetylcholine and the, D. Zimmet, 1070; Restropic Activity of, C. Wetzler-Ligeti, and Dr B. P. Wiesner, 1100
Blowing Up of a Sunken Vessel, [1838], 984
Bode, Kepler, Newton and, Prof. G. W. Todd, 412
Bode's Law and Saturn's Satellites, J. Miller, 245
'Bone Age' Man, Abbé Breuil, 651
Boron: Hydrides of, H. I. Schlesinger and A. B. Burg, 520; in the Organs of the White Lily, Distribution of, G. Bertrand and L. Silberstein, 886

Calcium: Trimetaphosphate, A. Boullé, 702; Carbonate, Solubility of, in Solutions of Ammonium Salts, G. Emschwiller and G. Charlot, 1028
Calculus, Prof. H. W. March and Prof. H. C. Wolff (*Review*), 668
Calcutta, Royal Botanic Garden, Completion of its 150th Year, 18
Cambridge University: conferment on Dr. S. Goldstein of title of Stokes lecturer in mathematics; award of the Adam Smith prize to S. R. Dennison, 89; approval of a grant for research on Corrosion Fatigue; W. B. Reddaway elected an official fellow of Clare College, 216; Educational Science in, 237; grant from the Rockefeller Foundation for research in Experimental Medicine; N. F. M. Henny appointed demonstrator in mineralogy and petrology; offer of his collection of birds' eggs by Dr. A. H. Evans; award of the Michael Perkins prize to I. L. Mason, 258; R. H. Angus appointed lecturer in engineering; Prof. A. R. Radcliffe-Brown appointed Frazer lecturer in social anthropology for 1938–39; H. E. Hinton appointed junior curator of the Museum of Zoology; award of the Raymond Horton-Smith prize to Dr. H. L. H. H. Green, 382; Prof. W. L. Bragg appointed Cavendish professor of experimental physics, 403; conferment of a doctorate on C. H. Waddington; P. van Zeeland appointed Alfred Marshall lecturer for 1938–39; award of grants from the Worts fund, 525; Prof. W. L Bragg elected a professorial fellow of Trinity College, and J. W. S. Pringle and K. H. Harrison fellows of King's College, 567; J. A. G. de Courcy appointed superintendent of the engineering workshops; Dr. J. C. Sinclair appointed a Frank Edward Elmore student; J. R. Robinson awarded the Allen scholarship, 618; Abstracts of Dissertations Approved for Degrees, 640; award of Smith's prizes to F. Hoyle and A. L. Yoxall and of Rayleigh prizes to G. L. Clark and G. S. Rushbrooke; additional teaching offices recommended, 660; E. W. O. Adkins, G. D. Channell and F. Wemyss Smith appointed demonstrators in anatomy, 843; Dr. G. R. Owst elected professor of education, 885; B. Cooper appointed demonstrator in engineering; Dr. D. H. Valentine and G. C. Evans elected fellows of St. John's College, 943; M. Black appointed lecturer in geology, W. W. Williams lecturer in geography, and C. Culpin demonstrator in agricultural engineering, 1028; Prof. Eileen Power elected an honorary fellow of Girton College, 1112
Camera and Notebook: With, A Naturalist's Calendar (1938), Edited by Phyllis Barclay-Smith and R. Zimmermann (*Review*), 7

Chitin, Penetration of Ultra-violet Rays through, Dr. G. Eloff and V. L. Bosazza, 608

Chloroprene, Isoprene, Butadiene and, X-Ray study of, at Low Temperature, Dr. C. J. B. Clews, 513

Chromatid Fusion, Delayed Mitosis and, H. N. Barber, 80

Chromium: Chloride, CrCl, Spectrum of, Dr. A. G. Gaydon and Dr. R. W. B. Pearse, 370; Bromine, Nickel and Titanium, Packing Fractions of, Dr. F. W. Aston, 1096

Chromosomes: Structure of, Dr. C. D. Darlington, 371; Double Structure of, Prof. R. R. Gates and S. V. Mensinkai, 607

"Clay": Sir William Bragg, 649; in a Vegetable Diet, G. ap Griffith, 793

Coal, Motor Spirit from, J. E. James; J. L. Strevens and A. C. Cross, 1058

Cocarboxylase, Vitamin B_1 and, Dr. S. Ochoa, 831

Codeine in Indian Opium, Dr. H. B. Dunnicliff, 207

Colchicine, Methylcholanthrene and, administered with Plant Extracts on the Rat, Effects of, Dr. L. Havas and E. Gal, 284

α-Copper-Zinc Alloys, A New Type of Structure in the, Prof. F. N. Rhines and A. M Montgomery, 413

Copper, Gilding of, among the Pre-Columbian Indians, P. Bergsøe, 829

Corticosterone, Chemical structure of, Marguerite Steiger and Prof. T. Reichstein, 202

Cosmic: Rays: Heavy Electrons in, Dr. E. J. Williams and E. Pickup, 684; and the Aurora of January 25–26, Prof. V. F. Hess, R. Steinmaurer and A. Demmelmair, 686; Heavy Electrons in, Dr. E. J. Williams and E. Pickup, 836; Hard and Soft Components of, Secondary Effects of the, Prof. B. Trumpy, 909; Radiation Measurements, High-Altitude, near the Magnetic Axis-Pole, Dr. H. Carmichael and E. G. Dymond, 910

Cosmological Theory, Dr. F. L. Arnot, 1142

Coupling, Karrer's Theory of, Dr. W. J. Hickinbottom and E. W. Lambert, 1056

Cozymase, Enzymic Dephosphorylation of, N. B. Das and Prof. H. v. Euler, 604

Craspedacusta sowerbii, in Eastern Canada, Occurrence of the Freshwater Medusa, late Prof. H. B. Fantham and Dr. Annie Porter, 515

Crepis capillaris, Heterochromatic (Inert) Regions in the Chromosomes of, Prof. D. Kostoff and N. Arutiunian, 514

Crystals, Rectifying Properties of, Prof. R. Deaglio, 1011

Cubic Crystal, $Ni(NO_3)_2.6NH_3$, Evidence of Abnormal Behaviour of NO_3 in the, S. H. Yu, 158

Cucumber Viruses 3 and 4, Proteins of, The Ultracentrifugation of the, Dr. W. C. Price and Dr. R. W. G. Wyckoff, 685

Culex fatigans, Salinity Tolerance and *p*H range of, A. R. Woodhill, 920

Culicinæ: Metamorphosis in the, Cytology of, Prof. C. Å. Berger, 834; Cytology of Metamorphosis in the, C. R. Ribbands, 920

Cyanamide, Action of, on Wool, Dr. J. B. Speakman, B. Nilssen and C. S. Whewell, 688

Cyanuric Acid, Crystal Structure of, E. H. Wiebenga and N. F. Moerman, 122

Cyclols from Simple Peptides, Possibility of the Formation of, Prof. K. H. Meyer and W. Hohenemser, 1138

Cystein, The Action of, on Respiration, Fermentation and Synthesis in Yeast Cells, Prof. J. Runnstrom and E. Sperber, 689

Cytochrome: *a* and Cytochrome Oxidase, Prof. D. Keilin and Dr. E. F. Hartree, 870; Oxidase, Prof. D. C. Harrison, 1101

d-Amino-acid Oxidase, Coenzyme of the, Dr. F. B. Straub, 603

Darwin Misunderstood, G. West; Sir Edward Poulton, 1102

Decomposition Reactions of Organic Compounds in the Gaseous State, Prof. C. N. Hinshelwood, 1010; Prof. M. W. Travers, 1145

Defect Lattices and Catalytic Activity, Dr. A. Taylor and Dr. J. Weiss, 1055

Deuteron: -Deuteron-Neutrons, Biological Effects of, H. Yamashita, 416; Cross-Sections of the, for the Electric and Magnetic Nuclear Photo-effect, Dr. H. v. Halban, jun., 644; Induced Radioactivity in Oxygen, T. Yasaki and S. Watanabe, 787

Di-Anol, a Dimeride of *p*-Propenyl-Phenol, Œstrogenic Activity of, N. R. Campbell, Prof. E. C. Dodds and W. Lawson, 78

Diffraction Gratings ruled in Metallic Films, R. C. Williams, 329

Dilleniaceæ, Vascular supply of the Pedicel and the Ovule in Species of, Kailash Chandra Misra, 204

Dimentia Nomenclatorica Americana, E. Heron-Allen, 558

Disaccharide-splitting Enzymes, Specificity of, Dr. J. Leibowitz and S. Hestrin, 552

Disintegration Processes by Cosmic Rays in Plates impregnated with Samarium, Prof. H. J. Taylor, D. Fraser and V. D. Dabholkar, 472

Dissimilarity, Similarity and, Dr. W. H. George, 1055

Doppler Effect of Nuclear Resonance Level, Dr. H. von Halban, jun., and Dr. H. Paxton, 116

Drosophila: *melanogaster*? Genetic Control of a Morphogenetic Substance in, B. Ephrussi, Yvonne Khouvine and S. Chevais, 204; *pseudo-obscura*, Mozaics of, Fertile Haploid Sectors by Partial Merogony in, Prof. F. A. E. Crew and Rowena Lamy, 923; Giant Salivary Gland Nuclei of, Development of the, S. L. Frolova, 1014

Dynamics, Classical, Reversibility of the Equations of, Prof. E. A. Milne and G. J. Whitrow, 905

Earth, Primitive, The Liquid State of the, Dr. A. Mercier, 201

Earth's Magnetic Field in the Ionosphere, The Lorentz Polarisation Term and the, Dr. D. F. Martyn and G. H. Munro, 159

Eddington's Fundamental Equation, H. C. Corben, 747

Electromagnetic: Propagation, Faraday on, Sir Joseph Larmor, 36; and Neutrino Fields, Connexion between, A. Sokolow; M. H. L. Pryce, 976

Electron: -Multiplier as an Electron-counting Device, Prof. Z. Bay, 284; Spinning, A non-radiating Motion of a, Dr. J. W. Weyssenhoff, 328; -Optical Crystal Patterns, Lecture-room demonstration of, Dr. W. G. Burgers and J. J. A. Ploos van Amstel, 370; Multiplier for Measuring Ionization Currents, Dr. W. H. Rann, 410; -Inertia Effects in Thermionic Tubes, A Method of Investigating, S. Kownacki and J. A. Ratcliffe, 1009; Multiplier as an Electron Counting Device, Prof. Z. Bay, 1011

Electronic Excitation Energy, Mechanism of Propagation of, and Photosynthesis in Plants, Dr. J. Weiss, 248

Electrons: Heavy, and the β-decay Nuclear Forces, Dr. H. J. Bhabha, 117; Heavy, in Cosmic Rays, Dr. E. J. Williams and E. Pickup, 684; 836

Emulsification, An Anomalous case of, D. F. Cheesman, A. King and Dr. J. N. Sugden, 1099
Epidermal Water-Content, Stomatal Movement and, Prof. D. Thoday, 164
Erythroblastosis, Treatment with Ascorbic Acid of the Plasma of a Fowl affected by, Dr. E. Morelli and Dr. A. Vercellone, 202
Ethical Declaration for the Times, An, L. L. Whyte, 827
Ethnographical Museums, G. A. Wainwright, 332; E. Barger, 374
Extra-Galactic Systems, Two near, J. H. Reynolds, 875
Faraday on Electromagnetic Propagation, Sir Joseph Larmor, 36
$FCBr_3$, $FCCl_3$ and, Interatomic Distances of, J. Wouters and Prof. M. de Hemptinne, 412
$FCCl_3$ and $FCBr_3$, Interatomic Distances of, J. Wouters and Prof. M. de Hemptinne, 412
Fisheries, British, Phosphate and the Solar Radiation Constant, Dr. W. R. G. Atkins, 77
Flavin and Phosphorylated Flavin, Separation of, A. Emmerie, 416
Fleas, The Jump of, G. I. Watson, 923
Florisbad Skull, The, Sir Arthur Keith, 1010
Fluid Viscosity, Light Scattering and, Sir C. V. Raman and B. V. Raghavendra Rao, 242
Fluorites, Coloured, Absorption Bands and Electron Transitions in, Prof. K. Przibram, 970
Foot-and-Mouth Disease, Carriers of, Prof. R. C. McLean, 828
Foraminifera, Modern Studies of the, Dr. W. A. Macfadyen, 750
Fossil Hail Impressions, Probable, in Natal Coal Measures (Middle Ecca Series), L. E. Kent, 835
Freshwater Fishes, Blindness in, Dr. W. Rushton; 289
Friction, Analysis of, Nature of Sliding and the, Dr F. P. Bowden and L. Leben, 691
Frogs, Albino, W. A. Smallcombe, 753
Gamma Rays, Canalization of, Prof. F. L. Hopwood and Dr. T. E. Banks, 687
Gammarus from Ireland, Forms of, D. M Reid, 690
Gaseous Mixtures at Solid Surfaces, Adsorption of, Dr. F. J. Wilkins, 1054
Genes in the Chromonemata, The Most Probable Place of Location of the, Prof. D. Kostoff, 749
Geodesic Postulate, A New Boundary Condition and the, Prof. V. V. Narlikar, 906
Glacial Periods, Mountain Strata, Isostasy and, Distortion of, Sir Joseph Larmor, 906
Glare, Effect of Veiling, on apparent Size and Distance, T. M. Martin and Dr. R. W. Pickford, 371
Glucolytic Enzyme System, Separation of the, from the Brain Cells and its Coenzymes, A. Geiger, 373
α-Glyceric Aldehyde and Tumour Glycolysis, Dr. B. Mendel, Frida Strelitz and Dorothy Mundell, 288
Glycogen Breakdown in Muscle Extract and Yeast Juice, H. Lehmann, 470
Graphite, Colloidal, An effect of X-Radiation on the ξ-Potential of, I. Kemp; Prof. J. A. Crowther, 609
Growth-promoting Substances, Absorption of, by Cuttings, T. H. Jackson, 835
Halteres of Flies as Gyroscopic Organs of Equilibrium, G. Fraenkel and J. W. S. Pringle, 919
Heavy Elementary Particles, Structure of, Prof. G. Beck, 609
Hedgehog Serum, Magnesium and Calcium Content of, during Hibernation, Dr. P. Suomalainen, 471
Helium: Liquid, Viscosity of, below the λ-point, Dr. P. Kapitza, 74; II: Liquid, Flow of, J. F. Allen and A. D. Misener, 75; Heat Flow in, New phenomena connected with, J. F. Allen and H. Jones, 243; Ionized, Relativistic Stark Effect of, Dr. B. Kullenberg, 244; Liquid, The λ-phenomenon of, and the Bose-Einstein Degeneracy, Dr. F. London, 643; II: on Glass, Transfer of, J. G. Daunt and Dr. K. Mendelssohn, 911; Liquid, Experiments with, A. K. Kikoin and B. G. Lasarew, 912; Transport Phenomena in, Dr. L. Tisza, 913; Liquid, Velocity of Sound in, Prof. E. F. Burton, 970
Herbivora, Gastro-Intestinal Tract of, Disintegration of Cell-wall Substances in the, F. Baker and R. Martin, 877
Heterochromatin at the Distal Ends of the Chromosomes in *Triticum monococcum*, Prof. D. Kostoff, 690
Heterotrophic Cells, Metabolism of, Function of Carbon Dioxide in the, Dr. J. W. Hes, 647
Histamine and the Action of the Thyroid Gland, Dr. F. Ellinger, 1014
Homoptera, Permian, and Procoptera, Structure of, Dr. F. M. Carpenter, 164
Hormones: Gonad-stimulating, Standardization of, P. G. Marshall, 605; Ovotrophic and Folliculoplasic, Dr. J. Freud, 1013
Horse Serum Pseudoglobulin, Normal, Enzymatic removal of bound Carbohydrate from, A. G. Ogston, 1056
Hydroxyl Frequency in Carboxylic Acids, M. M. Davies and Dr. G. B. B. M. Sutherland, 372
Indium Hydride, Band Spectrum of, Dr. B. Grundstrom, 555
Insect Survival, Activity and, Dr. K. Mellanby, 554
Insects: Aerial Drift of, Prof. A. C. Hardy and P. S. Milne, 602; 'Climbing Organs' in, Dr. V. B. Wigglesworth, 974; Control of, by Methallyl Chloride, C. J. Briejèr, 1099
Insulin in Cell-free Extracts, Action of, H. Lehmann, 690
Intermetallic Compounds in the Molten State, Stability of, Dr. E. Heymann and H. P. Weber, 1059
Ionized Air, Refractive Index and Conductivity of, Effect of Longitudinal Magnetic Field on the, Dr. S. S. Banerjee and B. N. Singh, 511
Ionosphere: Earth's Magnetic Field in the, The Lorentz Polarization Term and the, Dr. D. F. Martyn and G. H. Munro, 159; Medium Radio Waves in the, Magnetic Double Refraction of, Prof. E. V. Appleton, Dr. F. T. Farmer and J. A. Ratcliffe, 409; *E* region of the, Meteoric Ionization in the, Prof. A. M. Skellett, 472
Iron: Wire, Magnetic Quality of, as influenced by the Diameter, Dr. T. F. Wall, 205; Wire, Magnetic Quality of, Effect of Manganese Coating on the, Dr. T. F. Wall, 1016
Isomerism, A Novel Type of, in a Co-ordination Compound of Copper, D P. Mellor, G. J. Burrows and B. S. Morris, 414
Isoprene, Butadiene and Chloroprene, X-Ray study of, at Low Temperature, Dr. C. J. B. Clews, 513
Isostasy: Final, Distorted Mountain Strata in relation to, Sir Joseph Larmor, 603; Mountain Strata, and Glacial Periods, Distortion of, Sir Joseph Larmor, 906
K-Electron Capture, Nuclear Transformation by, Dr. E. J. Williams and E. Pickup, 199
Karrer's Theory of Coupling, Dr. W. J. Hickinbottom and E. W. Lambert, 1056
Kelsey Plums, Effect of Acetylene on the Ripening of, V. A. Putterill, 875
Kepler, Newton and Bode, Prof. G. W. Todd, 412
Keratin Molecule, Constitution of the, Dr. J. B. Speakman and E. Stott, 414
Ketones and Secondary Alcohols, Photochemical Interaction between, C. Weizmann, Y. Hirshberg and Dr. E. Bergmann, 1012
Kramers' Absorption Law in Astrophysical Problems, T. L. Page, 1137
Kurumi (Japan), Meteorite, The, F. Watson, jun., 475
Lactoflavin in the Eyes of Fish, E. Adler and Prof. H. v. Euler, 790
Lead, Supraconductive, Thomson Effect of, Dr. J. G. Daunt and Dr. K. Mendelssohn, 116
Leuconostoc dextranicum, The Polysaccharide produced from Sucrose by, Dr. S. Peat, Dr. M. Stacey and E. Schlüchterer, 876
Light: Diffraction of, by Supersonic Waves in Solids, N. S. Nagendra Nath and Prof. H. Mueller, 37; Scattering and Fluid Viscosity, Sir C. V. Raman and B. V. Raghavendra Rao, 242; Convergent Beams of, Illusion of, A. H. Rosenthal, 836; G. Colange and Dr. Y. Le Grand, 1059; Dr. A. H. Rosenthal, 1060
Lightning: Photography of, in Daytime, Dr. B. F. J. Schonland, 115; Strokes, Sir Joseph Larmor, 115

Lignifying Cells, The Oxidation-Reduction Potential in, K. Griffioen, 876

Lipin Phosphorus in Normal and Rachitic Rats, Formation of, with a Radioactive Phosphorus Isotope as an Indicator, Dr. M. J. L. Dols, Prof. B. C. P. Jansen, Prof. G. J. Sizoo and F. Barendregt, 77

Lipoid Films, Complex Formation in, Dr. J. H. Schulman, E. Stenhagen and Prof. E. K. Rideal, 785

Livestock Improvement, Acclimatization in relation to, Prof. R. Prawochenski, 922

Lodge, Prof. Alfred, E.A.G., 290

Logic, Science and Philosophy, Dr. H. Jeffreys, 977

Lorentz Polarization Term, The, and the Earth's Magnetic Field in the Ionosphere, Dr. D. F. Martyn and G. H. Munro, 159

Lycopene, Spontaneous Isomerization of, L. Zechmeister and P. Tuzson, 249

Lymphogranuloma Inguinale (Climatic Bubo), Developmental forms of the Virus of, Dr. G. M. Findlay, R. D. Mackenzie and F. O. MacCallum, 877

Magnetic Storms, Solar Eruptions, Auroras and, Recent, A. J. Higgs and R. G. Giovanelli, 746

Manganese, Role of, in the Biological Synthesis of Ascorbic Acid, M. N. Rudra, 203

Marine Egg Membranes, Electric Impedance of, Dr. K. S. Cole, 79

Martensite, Orientation Habit of, A. B. Greninger and A. R. Troiano, 38

Maxwell's Equations and the "Flux Cutting" Principle, Dr. J. A. Wilcken; Dr. C. V. Drysdale, 907

Mental Factors: Methods of Estimating, Prof. G. H. Thomson, 246; Dr. M. S. Bartlett, 609; Estimation of, by Regression, A Shortened Method of, Dr. W. Ledermann, 650

Mercury: Vapour, Toxicity of, to Insects, H. C. Gough, 922; Effects of Gas Ions on the Benedicks Effects in, Prof. C Benedicks and P. Sederholm, 1097

Mesomeric Systems, Formation of, Prof. J. Kenner, 786

Mesophyll of the Leaf, Nature of the Outer Surface of the Cell Walls of the, Prof. F. J. Lewis, 34

Metallic Protection, Selective Oxidation as a Fundamental Principle in, G. J. Thomas and L. E. Price, 830

Metallography: A New Technique, B. Chalmers and W. E. Hoare, 475

Metals: Structure of, Prof. W. L. Bragg and H. Lipson, 367; R. A. Stephen, 748

Methallyl Chloride, Control of Insects by, C. J. Briejèr, 1099

Methane Molecule, Structure of the, Dr. H. A. John and Dr. W. H. J. Childs, 916

Methylcholanthrene and Colchicine administered with Plant Extracts on the Rat, Effects of, Dr. L. Havas and E. Gal, 284

Mice, Male and Female, Adrenal Cortex differences in, Dr. Ruth Deanesly, 79; Dr. W. Cramer; Dr. Ruth Deanesly, 286

Microphones, Free Field Calibration of, A. J. King and C. R. Maguire, 1016

Milk-Wool, Dissolving Action of Micro-organisms on, Prof. J. Smit and B. van der Heide, 647; W. H. Glover, 1057

Millipedes, Cell Size in, H. G. Callan, 247

Molecules: Organic, Primary Photodissociation Processes of Mechanism of the, Dr. E. Bergmann and Prof. R. Samuel, 832, Prof. R. G. W. Norrish, 1138

Molybdenum, Action of, in Nutrition of Milking Cattle, W. S. Ferguson, Dr. A. H. Lewis and Dr. S. J. Watson, 553

Monochromator, A New, Prof. Y. Öhman, 157; 291

Monolayers, Viscosity of, The Surface Slit Viscosimeter and the, Prof. W. D. Harkins and Prof. J. G. Kirkwood, 38

Monomolecular Films, Viscosity of, D. G. Dervichian and M. Joly, 975

Morpholine, Dipole Moment and Structure of, Prof. J. R. Partington and D. I. Coomber, 918

Mosaic Crystal Imperfection Effect, Elimination of the, on the Width of X-Lines, J. M. Bačkovský, 872

Motor Spirit from Coal, J. E. James; J. L. Strevens and A. C. Cross, 1058

Mountain Strata, Isostasy and Glacial Periods, Distortion of, Sir Joseph Larmor, 906

Muscle Tissue, Molecular 'Rejuvenation' of, Prof. G. Hevesy and O. Rebbe, 1097

NO_3 in the Cubic Crystal, $Ni(NO_3)_2 \cdot 6NH_3$, Evidence of Abnormal Behaviour of, S. H. Yu, 158

N_2H^+ Ion, Direct Evidence for the, in the Discharge Reaction between N_2 and H_2, G. C. Eltenton, 975

Natal Coal Measures (Middle Ecca Series), Probable Fossil Hail Impressions in, L. E. Kent, 835

Negative Ions, Formation of, at Surfaces, Dr. R. H. Sloane and R. Press, 872; Dr. F. L. Arnot and C. Beckett, 1011

Nematode Larvæ, New Method for the Storage of, E. L. Taylor, 205

Neon and Argon in the Earth's Crust, Lord Rayleigh, 410

Neutrino, Electromagnetic and, Fields, Connexion between, A. Sokolow; M. H. L. Pryce, 976

Neutro-Electron Effect: Wilson Chamber photograph of the, S. Kikuchi and H. Aoki, 328; Wilson Chamber study of the, S. Kikuchi and H. Aoki, 645

Neutron: Proton and the, Magnetic Moments of the, Dr. H. F. Fröhlich and Dr. W. Heitler, 37; -Electron Interaction proposed by Kikuchi, G. T. Seaborg and D. C. Grahame, 1053

Neutrons, Group *A*, in Silver, Absorption of, Dr. H. Paxton, 971

Newton, Kepler, Bode and, Prof. G. W. Todd, 412

Nickel, Bromine, Chromium and Titanium, Packing Fractions of, Dr. F. W. Aston, 1096

Nicotinic Acid in Foodstuffs, A Colorimetric Method for the Estimation of, M. Swaminathan, 830

Nitrogen: High-pressure Afterglow in, Prof. J. Kaplan, 645; and Argon in the Earth's Crust, Lord Rayleigh, 970

Nitrogen: Line, A New, Prof. J. Kaplan, 1139; (^2P) in the High Atmosphere, Possible Presence of Metastable Atoms of, R Bernard, 1140

Noluas of Bengal, Blood Groups of the, Dr. M. N. Basu, 649

Nuclear: Field, Nature of the, Dr. N. Kemmer, 116; Resonance Level, Doppler Effect of, Dr. H. von Halban, jun. and Dr. H. Paxton, 116; Forces, Heavy Electrons and the β-Decay, Dr. H. J. Bhabha, 117; Transformation by *K*-electron Capture, Dr. E. J. Williams and E. Pickup, 199; Photo-effects, Prof. N. Bohr, 326; Forces, Magnitude of, Prof. G. Beck, 832; Photo-Effects, Resonance in, Prof. N. Bohr, 1096

Nucleic Acid-Protein Mixtures, Electrophoretic behaviour in, E. Stenhagen and Dr. T. Teorell, 415

Œstrogenic Activity of certain Synthetic Compounds, Prof. E. C. Dodds, L. Golberg, W. Lawson and Prof. R. Robinson, 247

Œstrone in Human Male Urine, Chemical Identification of, E. Dingemanse, E. Laqueur and O. Muhlbock, 927

Ophiothrix fragilis with in the Genital Bursa of the Adult, Occurrence of young, Dr. J. E. Smith, 554

Opium, Indian, Codeine in, Dr. H. B. Dunnicliff, 207

Optical Illusion, An, L. Pendred, 1018

Osmosis in Physics and Biology, Prof. E. Ernst, 80

Ostrea: *edulis*, New Pallial Sense Organs in Early Fixed Stages of, H. A. Cole, 161; *virginica*, Sources of Calcium for Shell of, Dr. P. S. Galtsoff, 922

Ounce Molecular Weight of a Gas, Dr. H. D. H. Drane, 791; J. Strachan; H. V. Thompson, 977

Oxygen, Deuteron-induced Radioactivity in, T. Yasaki and S. Watanabe, 787

Paramagnetic: Ions from Magnetic Measurements, Coupling between the Orbital and the Spin Angular Momenta of, Prof. K. S. Krishna and A. Bose, 329; Absorption, Stimulation of, by a Constant Field, F. Brons and Dr. C. J. Gorter. 369

Pars Nervosa of the Pituitary, Secretary Elements of the, M. Griffiths, 286

Partridge, Food of the, Dr. W. E. Collinge, 834

Pendulum, Rotating, Some Observations on the, B. H. Crawford, 792

Pentaerythritol, Amino-derivatives of, Dr. F. G. Mann and A. Litherland, 789
Peroxides, Organic, Decomposition of, E. J. Harris and Prof. A. C. Egerton, 472
Phase Rule Equation, A Modified, Dr. S. T. Bowden, 331
Philosophy, Science, Logic and, Dr. H. Jeffreys, 977
Phosphatases, Vitamin C and, K. V. Giri, 119
Photosynthesis in Plants, Mechanism of Propagation of Electronic Excitation Energy, and, Dr. J. Weiss, 248
Piltdown Bone Implement, The, J. Reid Moir, 926; Sir Arthur Smith Woodward, 1059
Pine Leaves, Relation between Structure of, and their Position on the Tree, Prof. M. Moissejewa, 649
Plant Growth Hormones, Physiological Curve of Response to, N. H. Grace, 35; Virus Preparation, A, in a fully Crystalline State, F. C. Bawden and N. W. Pirie, 513
Plants, Net Assimilation Rate in, Drift of, O. V. S. Heath, 288
Polar Liquid-Liquid Interfaces, Adsorption Potentials at, G. Ehrensvard and L. G. Sillén, 788
Pomatoceros triqueter (L.), Tube Formation in, J. D. Robertson and Dr. C. F. A. Pantin, 648
Potato: Dietary, A Clay adjunct to, Dr A. Lawson and H. P. Moon, 40; Virus X, Mode of dissemination of, J. B. Loughnane and Dr. P. A. Murphy, 120
Prague Sero Reactions for Cancer, The, F. Bergh, Dr. O. M. Henriques and J. Schousboe, 751
Proton and the Neutron, Magnetic Moments of the, Dr. H. Frohlich and Dr. W. Heitler, 37
Protons in the Universe, Mean Free Path of, Prof. E. Schrodinger, 410
Psocoptera, Permian Homoptera and, Structure of, Dr. F. M. Carpenter, 164
Pterinopecten papyraceus and "*Strophomena*" *pecten*, Dr. A. Wood, 1100
Puccinia graminis, Fusions between Flexuous Hyphæ and Pycnidiospores in, Prof. A. H. R. Buller, 33
Purple, Visual, Scotopic Luminosity Curve and the Absorption Spectrum of, E. Ludvigh, 1141
Pyridine, Dipole Moment of, B. A. Middleton and Prof. J. R. Partington, 516
Pyrrolidone: a Chemical Group of particular significance to Differentiation, Dr. F S. Hammett, 82
Quantum Theory, Relativity and, Prof. Max Born, 327
Racemic Compound, A New Method of resolving a, G. M Henderson and Dr. H. G. Rule, 917
Radiation, Laws of, Cooling Curves and the, C. Handford, 368
Radioactivity produced in Scandium by Fast Neutrons, W. E. Burcham, M. Goldhaber and R. D. Hill, 510
Radio: Frequencies on Supraconductors, Some Experiments at, Dr. F. B. Silsbee, Dr. F. G. Brickwedde and R. B. Scott, 75; -Phospholipid, Formation of, by Isolated Tissues of the Rat, A. Robinson, I. Perlman, S. Ruben and Prof. I. L. Chaikoff, 119; Waves: Medium in the Ionosphere, Magnetic Double Refraction of, Prof. E. V. Appleton, Dr. F. T. Farmer and J. A. Ratcliffe, 409; Short, Deviations of, from the London-New York Great Circle Path, C. B. Feldman, 510; Low-frequency, Effect of Catastrophic Ionospheric Disturbances on, R. Bureau, 646; -Element $^{32}_{15}$P in Weighable Quantity by means of an Electric Field, J. Govaerts, 871; -Elements, Artificial, Photographic action of, C. Groven, J. Govaerts and Prof G. Guében, 916, -Element $^{32}_{15}$P, Preparation of, by Means of an Electric Field, J. Govaerts, 1103
Ranikot Sea, Westward Extension of the, Lt.-Col. L. M. Davies, 202
Reduviidæ (Rhynchota), Function of the 'Fossula Spongiosa' or Spongy Furrow in, N. C. E. Miller, 749
Relativity and Quantum Theory, Prof. Max Born, 327
Reptiles and Fish, Ears of, Potential Changes in the, Prof E. D. Adrian, 553
Rhodium, Radio, Isomeric Forms of, Dr. B. Pontecorvo, 785
Rotating Pendulum, Some Observations on the, Dr. R. J. Lythgoe, 474
Rubber, Elastic Constituent of, Dr. T. C. Roberts (née Marwick), 834
Rutherford in Manchester, Memories of, Prof. H. Geiger, 244
Sabellid Worms, Functions of the Tube in, Prof. H. Munro Fox, 163
Salicylaldehyde Reaction of Csonka-Straub, Specificity of the, Dr. T. Thomson, 917
Salmon (*Salmo salar* L.), Life-history of the, Prof. J. H. Orton and J. W. Jones, 1017
Saturn's Satellites, Bode's Law and, J. Miller, 245
Scandium, Radioactivity Produced in, by Fast Neutrons, W. E. Burcham, M. Goldhaber and R. D. Hill, 510
Schutz's Law and the Clotting of Blood, Dr. T. Astrup, 1057
Science: and Society, The Advancement of, Dr. F. R. Moulton, 517; and the Unobservable, S. Van Mierlo, 555; Prof. E. H. Kennard, 556; Prof. H. Dingle, 557; and Society, The Advancement of, Prof. P. G. H. Boswell, Prof. F. T. Brooks and Prof. A. Ferguson, 557; Social Relations of, Sir William Bragg; Sir F. Gowland Hopkins; H. G. Wells; Prof. J. L. Myres, 725; Prof. H. J. Flaure; Prof. P. S. Florence, 726; Prof. H. A. Marquand; Prof. H. J. Laski; Prof M. Ginsberg, 727; A. Farquharson; Prof. C. Spearman; Prof. J. C. Flugel, 728; Dr. C. S. Myers; Prof. F. C. Bartlett; Prof. A. V. Hill, 729; Prof. J. S. B. Stopford; Prof. J. B. S. Haldane, 730; Sir Peter Chalmers Mitchell; Prof. W. E. Le Gros Clark; Prof. J. Graham Kerr, 731; Prof. J. A. Ryle; Prof. F. A. E. Crew, 732; Prof. E. J. Salisbury; Dr. J. S. Huxley, 733; Dr. J. Needham; Sir Daniel Hall; Sir John Russell, 734; Prof. P. G. H. Boswell; Sir Henry Tizard, 735; Prof. J. D. Bernal; Prof. P. M. S. Blackett, 736; Prof. F. A. Lindemann; Prof. H. Levy, 737; Prof. A. Ferguson; Sir Richard Paget, Bt., 738; Prof. A. C. G. Egerton, 739; Prof. F. G. Donnan, 740; Prof. J. Read; Dr. C. H. Desch, 741; Prof. F. Soddy, 784; Dr. W. A. Wooster, 879, and the Unobservable, Prof. E. H. Kennard; Prof. H. Dingle, 878; Logic and Philosophy, Dr. H. Jeffreys, 977; Subjects at External Arts Examinations, A. Mole, 978
Seasons, Nomenclature of the, Dr. C. H. Pollog, 206
Seismic Waves in the Core of the Earth, Prof. B. Gutenberg and C. F. Richter, 371
Sense Organs, Autonomous Rhythmical Activity of, A. Sand, 285
Sex Hormones, Terminology of, Dr. A. S. Parkes, 36, 73
Sheep: Selective Thallium Moult in, Prof. N. A. Iljin, 162; Tick, Activity of the, Prof. J. Hendrick, W. Moore and G. D. Morison, 648
Silicon: Poisoning in the, A Curious Case of Supposed, E. Gray, 163; Monosulphide, Band Spectrum of, R. F. Barrow and Dr. W. Jevons, 833
Similarity and Dissimilarity, Dr. W. H. George, 1055
Sliding, Nature of, and the Analysis of Friction, Dr. F. P. Bowden and L. Leben, 691
Social: Studies, Realistic, Sir William Beveridge, 375; Relations of Science, Sir William Bragg; Sir F. Gowland Hopkins; H. G. Wells; Prof. J. L. Myres, 725; Prof. H. J. Fleure; Prof. P. S. Florence, 726; Prof. H. A. Marquand; Prof. H. J. Laski; Prof. M. Ginsberg, 727; A. Farquharson; Prof. C. Spearman; Prof. J. C. Flugel, 728; Dr. C. S. Myers; Prof. F. C. Bartlett; Prof. A. V. Hill, 729; Prof. J. S. B. Stopford; Prof. J. B. S. Haldane, 730; Sir Peter Chalmers Mitchell; Prof. W. E. Le Gros Clark; Prof. J. Graham Kerr, 731; Prof. J. A. Ryle; Prof. F. A. E. Crew, 732; Prof. E. J. Salisbury; Dr. J. S. Huxley, 733; Dr. J. Needham; Sir Daniel Hall; Sir John Russell, 734; Prof. P. G. H Boswell; Sir Henry Tizard, 735; Prof. J. D. Bernal; Prof. P. M. S. Blackett, 736; Prof. F. A. Lindemann; Prof. H. Levy, 737; Prof. A. Ferguson; Sir Richard Paget, Bt., 738; Prof. A. C G. Egerton, 739; Prof. F. G. Donnan, 740; Prof. J. Read; Prof. J C. Philip; Dr. C. H. Desch, 741; Prof. F. Soddy, 784; Dr. W. A. Wooster, 879
Society: Science and, The Advancement of, Dr. F. R. Moulton, 517; Prof. P. G. H. Boswell, Prof. F. T. Brooks and Prof. A. Ferguson, 557

Sodium: in the High Atmosphere, R. Bernard, 788; Prof. J. Cabannes, Prof. J. Dufay and J. Gauzit, 1054
Soils of Southern England, Pedocalic Tendencies in, Dr. Frances F. Kay, 925
Solar: Radiation Constant, British Fisheries, Phosphate and the, Dr. W. R. G. Atkins, 77; Corona? Does Iron Occur in the, Prof. A. Rubinowicz; Prof. F. J. M. Stratton, 81; Eruptions, Auroras, and Magnetic Storms, Recent, A. J. Higgs and R. G. Giovanelli, 746
Sound Film, Variable-width Properties of, as an Optical Diffraction Grating, Dr. J. F. Schouten, 914
Soviet: Universities, Salaries in, Dr. L. H. Callendar, 290; M. Ruhemann, 792
Species Hybrids, Failure of Anaphase Separation in, H. Klingstedt, 606
Spruce Sawfly, Cytology of, and its Control in Eastern Canada, Dr. Stanley G. Smith, 121
Stark Effect, Relativistic, of Ionized Helium, Dr. B. Kullenberg, 244
Stellar Energy, Origin of, Dr. L. Landau, 333
Stick Insects, Eggs of, Sister Monica (Dr. Monica Taylor), 1059
Stomatal Movement and Epidermal Water-content, Prof. D. Thoday, 164; F. J. Nutman; Prof. D. Thoday, 608
"*Strophomena*" *pecten*, *Pterinopecten papyraceus* and, Dr. A. Wood, 1100
Succinic Acid, Effect of, on the Respiration of Normal Human Muscle and various Myopathies, Dr. F. J. Stare, E. S. Gordon and M. J. Musser, 831
Sugarcane x Bamboo Hybrids, Chromosome Numbers in, E. K. J. Ammal, 925
Sulphur Content of the Intercellular Phase of the Wool Fibre, Dr. J. B. Speakman and Dr. P. R. McMahon, 118
Summer Drought in Caves, Effect on Organisms of, R. S. Hawes, 607
Sun: The Apparent Size of the, A. P. Trotter, 123; Apparent Enlargement of the, at the Time of Rising and Setting, Capt. C. J. P. Cave, 290
Sunbeams, 'Convergent', J. J. Hopfield, 333; Dr. A. C. Klebs; A. E. Moon; A. P. Trotter, 558; W. M. Witchell, 559; J. E. Jackson, 1102
Superlattices, Stability of, Factors Influencing, R. Hultgren and L. Tarnopol, 473
Supraconductors, The Intermediate State of, Dr. L. Landau, 688
Swan, Supposed Silicon Poisoning in the, A Curious Case of, E. Gray, 163
Telepathy, Scientific Tests of, Surg.-Rear-Admiral C. M. Beadnell, 878
Terrestrial Life", "Foundations of, Prof. F. Allen, 610
Thermal Conductivity at Low Temperatures, Prof. W. J. de Haas, 1053
Thermal Expansion and 'Co-operative Phenomena', Dr. R. Eisenschitz, 1143
Thermionic Valves, Fluctuation Noise in, D. A. Bell, 833
Thomson Effect of Supraconductive Lead, Dr. J. G. Daunt and Dr K. Mendelssohn, 116
Thymonucleic Acid: Molecular Shape and Size of, R. Signer, Prof. T. Caspersson and Prof. E. Hammarsten, 122; X-Ray Study of, Dr. W. T. Astbury and Florence O. Bell, 747
Thyroid Gland, Histamine and the Action of the, Dr. F. Ellinger, 1014
Titanium, Bromine, Chromium, Nickel and, Packing Fractions of, Dr. F. W. Aston, 1096
α-Tocopherol (Vitamin E), Synthesis of, Prof. P. Karrer, H. Fritzsche, B. H. Ringier and H. Salomon, 1057
β-Tocopherol, Structure of, Vitamin E: Dr. F. Bergel, A. Jacob, Dr. A. R. Todd and T. S. Work; Dr. J. F. Danielli, 646
Triticum monococcum, Heterochromatin at the Distal Ends of the Chromosomes in, Prof. D. Kostoff, 690
Tumour Glycolysis, *d*-Glyceric Aldehyde and, Dr. B. Mendel, Frida Strelitz and Dorothy Mundell, 288
Ultracentrifuge: Sedimentation Curves, Direct Photography of, J. St. L. Philpot, 283; A Simple Inexpensive, Prof. J. W. McBain and F. A. Leyda, 913
Ultra-violet Rays, Penetration of, through Chitin, Dr. G. Eloff and V. L. Bozazza, 608
Urea: Excretion, present Clearance-Reabsorption Views of, A Contradiction in the, Prof. E. J. Conway, 471; Possible role of, in formation of Cancerous Growths, J. C. M. Gardner, 692
Uricase, Purified, Dr. J. N. Davidson, 790
Vibrio, Spore formation in a, Dr. R. L. Starkey, 791
Viscosimeter, The Surface Slit, and the Viscosity of Monolayers, Prof. W. D. Harkins and Prof. J. G. Kirkwood, 38
Vitamin B_1, Quantitative Measurement of, by the Thiochrome Reaction, Dr. M. Pyke, 1141
Vitamin: C and Phosphatases, K. V. Giri, 119; A, Absorption Spectrum of, Effect of Solvents on the, E. Lester Smith, Babette E. Stern and F. E. Young, 551; Dr. R. A. Morton, 552; E: Structure of β-Tocopherol, Dr. F. Bergel, A. Jacob, Dr. A. R. Todd and T. S. Work; Dr. J. F. Danielli, 646; B_1 and Cocarboxylase, Dr. S. Ochoa, 831; E, Synthesis of α-Tocopherol, Prof. P. Karrer, H. Fritzsche, B. H. Ringier and H. Salomon, 1057
Water, Heavy, Constitution of, Dr. I. Ramakrishna Rao and P. Koteswaram, 331
Wax Insect of China, Staunton on the, S. Mahdihasran, 924
Whale: Shark, A, rammed by a Vessel off the Pacific Coast of Western Panama, Dr. E. W. Gudger, 516; Story, A, A S. E. Ackermann, 752
Wilson Chamber: Photograph of the Neutro-Electron Effect, S. Kikuchi and H. Aoki, 328; Study of the Neutro-Electron Effect, S. Kikuchi and H. Aoki, 645
Winter Heating?, Why do we have, Prof. R. Emden, 908
Wireless Interferometer, A, T. L. Eckersley, 369
Wood, Relation of Strength of, to Shrinkage, W. W. Barkas and H. Q. Golder, 874
Wool: Fibre, Intercellular Phase of the, Sulphur Content of the, Dr. J. B. Speakman and Dr. P. R. McMahon, 118; Action of Cyanamide on, Dr. J. B. Speakman, B. Nilssen and C. S. Whewell, 688
Yeast Cells, Respiration, Fermentation and Synthesis in, The Action of Cystein on, Prof. J. Runnstrom and E. Sperber, 689
Young's Modulus, Value of, for Nickel Wire as influenced by the Diameter, Dr. T. F. Wall, 751
Zellerella, An Opalinid Ciliate, in South Africa, Occurrence of, Dr. H. Sandon, 1143
Zirconium, α- into β-, Electron-Optical Observation of the Transition of, Dr. W. G. Burgers and J. J. A. Ploos van Amstel, 330
Zodiacal Light: The, at a Total Solar Eclipse, Prof. C. H. Smiley, 121; Origins of the, Sir Joseph Larmor, 201

Corticosterone, Chemical Structure of, Marguerite Steiger and Prof. T. Reichstein, 202
Cosmic: Dust Cloud, Evolution of a, Prof. Hildebrand, 377; Ray Intensity, Variation of, on the Hafelekar, according to Local and Sidereal Time, A. Demmelmair, 385; Rays, Heavy Particles in, Photographic Investigation of, Marietta Blau and Hertha Wambacher, 385; Ray Showers, Production of, M. A. Starr; R. B. Brode and M. A. Starr, 561; Rays: Heavy Electrons in, Dr. E. J. Williams and E. Pickup, 684; and the Aurora of January 25–26, Prof. V. F. Hess, R. Steinmaurer and A. Demmelmair, 686; Heavy Electrons in, Dr. E. J. Williams and E. Pickup, 836; Radiation, Some Properties of the Penetrating Fraction of the, Mme. Thérèse Grivet-Meyer, 886; Rays, Hard and Soft Components of, Secondary effects of the, Prof. B. Trumpy, 909; Radiation Measurements, High-Altitude, near the Magnetic Axis-Pole, Dr. H. Carmichael and E. G. Dymond, 910; Ray Shower, Ultra-hard, New kind of, K. Schmeise and W. Bothe, 982; Rays, Prof. P. M. S. Blackett and others; Dr. E. J. Williams, 1085
Cosmological Theory, Dr. F. L. Arnot, 1142
Cosmology, The Observational Approach to, Dr. E. Hubble (*Review*), 446

Cotton: World, Production and Trade, 30; Lintless Mutations in, J. B. Hutchinson and P. D. Gadkari, 795
Coupling, Karrer's Theory of, Dr. W. J. Hickinbottom and E. W. Lambert, 1056
Cozymase, Enzymic Dephosphorylation of, N. B. Das and Prof. H. v. Euler, 604
Crabs of America, Miss Mary J. Rathbun, 651
Craspedacusta sowerbii in Eastern Canada, Occurrence of the Freshwater Medusa, late Prof. H. B. Fantham and Dr. Annie Porter, 515
Crepis capillaris, Chromosomes of, Heterochromatic (Inert) Regions in the, Prof. D. Kostoff and N. Arutiunian, 514
Cresol Blue (Tyrosinase, Paracresol, Amino Acids), F. Chodat and P. Brunschwig, 845
Crop Production without Soil, Prof. W. F. Gericke, 536
Crustacea: from the 'Discovery' Expedition, Research on, 297; of the Philippines, P. E. Eulogio, 336
Crystal: Chemistry, F. Machatschki, 520; Mixed, Segregation of the Constituents of a, R. Becker, 981
Crystals: Glide in, Prof. E. N. da C. Andrade and L. C. Tsien; L. C. Tsien and Y. S. Chow, 85; Rectifying Properties of, Prof. R. Deaglio, 1011
Cuban Society: of Biology, Dr. H. H. Volcrers elected an honorary member of the, 550; of Natural History, Prof. H. Boker elected an honorary member of the, 550
Cubic Crystal, $Ni(NO_3)_2 \cdot 6NH_3$, Evidence of Abnormal Behaviour of NO_3 in the, S. H. Yü, 158
Cucumber Viruses 3 and 4, The Ultracentrifugation of the Proteins of, Dr. W. C. Price and Dr. R. W. G. Wyckoff, 685
Cucurbitaceæ, Peculiar Cystoliths in the, Dr. H. L. Chakravarty, 336
Culex fatigans, Salinity Tolerance and pH range of, A. R. Woodhill, 920
Culicinæ, Cytology of Metamorphosis in the, Prof. C. A. Berger, 834; C. R. Ribbands, 920
Curie, Madame: Eve Curie. Translated by V. Sheean (*Review*), 1079; Biography of, Prof. L. Wertenstein (*Review*), 1079
Curtis's Botanical Magazine, 1093
Current Titles, Part 1, 197
Cyameluric Acid, Hydromelonic Acid and related substances, Structure of, L. Pauling and J. H. Sturdivant, 385
Cyanamide, Action of, on Wool, Dr. J. B. Speakman, B. Nilssen and C. S. Whewell, 688
Cyanuric Acid, Crystal Structure of, E. H. Wiebenga and N. F. Moerman, 122
Cyclols from Simple Peptides, Possibility of the Formation of, Prof. K. H. Meyer and W. Hohenemser, 1138
Cyprus Fungi, A First List of, Dr. R. M. Nattrass, 612
Cystein, Action of, on Respiration, Fermentation and Synthesis in Yeast Cells, Prof. J. Runnstrom and E. Sperber, 689
Cytochrome: *a* and Cytochrome Oxidase, Prof. D. Keilin and Dr. E. F. Hartree, 870; Oxidase, Cytochrome *a* and, Prof. D. Keilin and Dr. E. F. Hartree, 870, Oxidase, Prof. D. C. Harrison, 1101
Czech Astronomical Observations, 1021

d-Amino-acid Oxidise, Coenzyme of the, Dr. F. B. Straub, 603
Dactylotheca plumosa Artis and *Senftenbergia ophiodermatica* Göppert, Structural features of, N. W. Radforth, 760
Darwin: Charles, The Fragmentary Man, G. West (*Review*), 807; Misunderstood, Sir Edward Poulton (*Review*), 807; G. West; Sir Edward Poulton, 1102; Medal, A discontinued, T. E. James, 960
De Bilt Seismological Station, Twenty-second Report of the, 155
Decibels and Phons, 237
Deciduous Fruits, Plant parts of, which give evidence of being Favourable for Tissue Culture, H. B. Tukey, 133
Decomposition Reactions of Organic Compounds in the Gaseous State, Prof. C. N. Hinshelwood, 1010; Prof. M. W. Travers, 1145
Defect Lattices and Catalytic Activity, Dr. A. Taylor and Dr. J. Weiss, 1055
Demavund, Peak of, Ascent of the, [1838], 89
Dementia Nomenclatorica Americana, E. Heron-Allen, 558
Democracy, An Educated, 487
Dermatophyte Fungi, Spiral Hyphæ of, A. M. Davidson and P. H. Gregory, 209
Descartes' Discourse on Method, Prof. L. Roth (*Review*), 769
Desert Locust in Arabia, R. C. Maxwell-Darling, 376
Deuteron: -Deuteron-Neutrons, Biological effects of, H. Yamashita, 416; Cross-sections of the, for the Electric and Magnetic Nuclear Photo-effect, Dr. H. v. Halban, jun., 644; -induced Radioactivity in Oxygen, T. Yasaki and S. Watanabe, 787
Dewar Flasks, P. L. Violle, 90
Di-Anol, Œstrogenic activity of, a Dimeride of *p*-Propenyl-Phenol, N. R. Campbell, Prof. E. C. Dodds and W. Lawson, 78
Dietetics and Social Problems, 280
Differential Equations, Mechanical Integration of, Prof. D. R. Hartree, 129
Diffraction: Gratings ruled in Metallic Films, R. C. Williams, 329; Conditions at the Limits in Problems of, by Periodic Media, J. Patry and J. Weigle, 427; by Irregular Gratings, R. W. Ditchburn, 526
Dilleniaceæ, Vascular supply of the Pedicel and the Ovule in species of, Kailash Chandra Misra, 204
Dioscorea, Genus, in the East, An account of the, Part 1: The Species which Twine to the Left, Sir David Prain and I. H. Burkill (*Review*), 182
Diphtheric Anatoxin, Disappearance of the Vaccinating Power of, in the presence of Antidiphtheric Serum, A. Besredka, 619
Disaccharide-splitting Enzymes, Specificity of, Dr. J. Leibowitz and S. Hestrin, 552
Discontinuities in the Flow of Liquids in Tubes, G. Heinrich, 259
"Discovery" Expedition, Research on Crustacea from the, 297
Discovery, New format of, 679
Disintegration Processes by Cosmic Rays in plates impregnated with Samarium, Prof. H. J. Taylor, D. Fraser and V. D. Dabholkar, 472
Dissimilarity, Similarity and, Dr. W. H. George, 1055
Dogmatic Spirit in Physics, The Pragmatic and the, Prof. J. Stark, 770
Dominion Tributes to the late Lord Rutherford, 841
Doppler Effect of Nuclear Resonance Level, Dr. H. von Halban, jun., and Dr. H. Paxton, 116
Dorset Heaths, Soil Toxicity in the, 798
'Dowtherm' Mixture, 1049
Drosophila: *melanogaster* ?, Genetic Control of a Morphogenetic Substance in, B. Ephrussi, Yvonne Khouvine and S. Chevais, 204; *pseudo-obscura*, Fertile Haploid Sectors by Partial Merogony in Mosaics of, Prof. F. A. E. Crew and Rowena Lamy, 923; Giant Salivary Gland, Nuclei of, Development of the, S. L. Frolova, 1014; X-Rayed, White-eye Mutation in, Magnitude of cell 'Sensitive Volume' associated with the, C. P. Haskins and E. V. Enzmann (3), 1071; *virilis*, Intersexuality in, and its Bearing on Sex Determination, G. A. Lebedeff, 1155
Druidical Temples, [1838], 383
Dry Rot in Ships, Effects of, Dr. J. Ramsbottom, 640
Drying, Intensive, Effects of, D. A. Lacoss and A. W. C. Menzies, 337
Dryopithecus, Teeth and Jaws of, Dr. W. K. Gregory, Dr. M. Hellman and Dr. G. E. Lewis, 1061
Dublin: Zoo and Bird Sanctuary, Report of the, 279; Zoological Society, [1838], 526
Ducheune de Boulogne Academy, award of the annual prize of the, to Dr. L. Bory, 156
Duffer, The Complete, B. L. Gimson and others, 130
Dundee University College: impending retirement of Prof. A. McKenzie, 320; Dr. W. F. K. Wynne-Jones elected professor of chemistry, 821
Dynamics, Classical, Reversibility of the Equations of, Prof. E. A. Milne and G. J. Whitrow, 905

Earle (Henry), (1789–1838), 131

Earth: Currents and Magnetic Disturbances, J. Bosler, 986; -Lore: Geology without Jargon, Prof. S. J. Shand. Second edition (*Review*), 142; Primitive, The Liquid State of the, Dr. A. Mercier, 201; Heat of the, [1838], 215

Earthquake: Records at De Bilt, 155; in the East Indies, 261; New Zealand, of June 17, 1929, J. Henderson, 294; in Anatolia on April 19, 779; A Large, Recorded at Kew Observatory, 969; of June 11, 1090

Earthquakes: and Atmospheric Pressure, R. C. Hayes, 167; of the Channel Islands, A. E. Mourant, 252; Deep-focus, Distribution of, B. Gutenberg and C. F. Richter, 694; Secondary Causes of, V. Conrad; R. Z. Kirkpatrick, 795; New Zealand, of 1934, R. C. Hayes, 838

Earthworms, South African (*Review*), 452

Earth's Magnetic Field in the Ionosphere, The Lorentz Polarization Term and the, Dr. D. F. Martyn and G. H. Munro, 159

East Africa, Prehistoric Mines in, Dr. L. S. B. and Mrs. Leakey, 965

East Malling Research Station, Extension of the, 1090

Easter Island Inscriptions, Dr. A. Metraux, 292

Ebro and Zi-Ka-Wei Observatories, 822

Ecology: in Town and Classroom, Dr. R. Bracher (*Review*), 392; Human (*Review*), 853

Economic and Social Research, Institute of, formation of an, with Sir Josiah Stamp as president and Prof. N. F. Hall as director, 69

Economics: Quantitative, Prof. R. Ray, 640; Lament for, Mrs. Barbara Wootton (*Review*), 996

Economists Arraigned, J. W. F. Rowe (*Review*), 996

Eddington's Fundamental Equation, H. C. Corben, 747

Edinburgh University: conferment of doctorates on Kalipada Biswas and S. S. Munro, 216; W. M. H. Greaves appointed professor of astronomy in, 236; award of the Dewar research fellowship to Dr. C. A. Beevers, 299; award of the Cameron prize to Dr. K. Landsteiner, 382; 1008; Dr. A. Mahr appointed Robert Munro lecturer in anthropology and prehistoric archæology for 1938–39, 588

Education: Post-Primary, Methods of Selection for, Dr. W. P. Alexander, 110; Current issues in, S. Vanderhook, 324; Changing Conceptions of, A. E. Henshall, 637; Selection and Training for Positions of Responsibility and Control, Report on, W. R. Dunlop, 1132

Educational Research, The Methodology of, Prof. C. V. Good, Prof. A. S. Barr and D. E. Scales (*Review*), 494

Egypt: Irrigation in, 298; Meteorology in, W. D. Flower, 376

Eights: James, a Pioneer Antarctic Naturalist, Dr. W. T. Calman, 72

Einstein-Eddington Conception of Curved Space, Fallacies underlying the, A. Eagle, 679

Electric: Telegraph, Visions of the extension of the, [1838], 47; Supply, Interruptions of, Safeguards against, H. W. Clothier, B. H. Leeson and H. Leybourn, 111; Field in Clouds, Exploration of the, Sir George Simpson and F. J. Scrase; Dr. F. J. W. Whipple, 143; Currents, Transient, Prof. H. H. Skilling (*Review*), 460; Locomotives, Trend of Design of, C. E. Fairburn, 1134

Electrical: Engineers, Institution of, award of the Faraday medal to Sir John Snell; F. Gill elected an honorary member, 198; Machines, Determination of the Coefficients of Leak of, P. Rossier, 845; Power, Evolution of, Dr. A. P. M. Fleming (Faraday lecture), 931; Engineers, Institution of, Report of the; awards of the, 933; Interference with Radio Reception, A. J. Gill and Dr. S. Whitehead, 941; and Allied Industries Research Association, Seventeenth Annual Report, 1050

Electricity: Technical, Principles and Practice, J. E. Phillips and Dr. R. W. B. Stephens (*Review*), 393; Plasticity and Structure of Matter, Dr. R. Houwink. With a chapter on the Plasticity of Crystals, by Dr. W. G. Burgers (*Review*), 810

Electrification, Rural, J. S. Pickles, 281

Electromagnetic: Propagation, Faraday on, Sir Joseph Larmor, 36; and Neutrino Fields, Connexion between, A. Sokolow; M. H. L. Pryce, 976

Electron: Showers, production of, by Cosmic Rays, H. J. Bhabha, 90; -Multiplier as an Electron-counting Device, Prof. Z. Bay, 284; Spinning, A non-radiating Motion of a, Dr. J. W. Weyssenhoff, 328; -Optical Crystal Patterns, Lecture-room Demonstration of, Dr. W. G. Burgers and J. J. A. Ploos van Amstel, 370; -Multiplier for Measuring Ionization Currents, Dr. W. H. Rann, 410; Tubes in Industry, K. Henney. Second edition (*Review*), 494; Diffraction and Surface Structure, Prof. G. I. Finch, 547; Optics, R. Fritz, 867; -Inertia Effects in Thermionic Tubes, A Method of investigating, S. Kownacki and J. A. Ratcliffe, 1009; Counting Device, Electron Multiplier as an, Prof. Z. Bay, 1011; Multiplier as an Electron Counting Device, Prof. Z. Bay, 1011

Electronic Excitation Energy, Mechanism of Propagation of, and Photosynthesis in Plants, Dr. J. Weiss, 248

Electrons: Heavy, Nuclear Forces and the β-Decay, Dr. H. J. Bhabha, 117; Heavy, in Cosmic Rays, Dr. E. J. Williams and E. Pickup, 684; 836; Fast, Absorption of, A. J. Ruhlig and H. R. Crane, 1021; in Pure Liquids, Visible Radiation of, P. A. Cherenkov, 1106

Electrostatic Charges, Densities of, A Method of measuring the, R. Pinoir, 300

Elektrotechnische Bericht. Band 4, Heft 6, 15 Januar, 1938 (*Review*), 1123

Elements in Sea Water, Spectrographic search for traces of, J. Bardet, A. Tchakirian and Mlle. Raymonde Lagrange, 660

Elephant, Fœtal Asiatic, Structure of, Prof. W. C. Osman Hill, 1062

Elm Disease in Great Britain, Leaflet on, 612

Elodea densa: Relation between Irradiation and Photosynthesis in, H. Hausner, 1070; Variation of the production of Oxygen with the Intensity of Illumination in Photosynthesis by, H. Hausner, 1071

Elsloo Beds, Age of the, Miss W. A. E. van de Geyn, 133

Empire: The Second City of the, Dr. P. C. Bagchi, 322; Exhibition, Glasgow, Science and Industry at the, 860

Employment in Great Britain, Statistics of, 1046

Emulsification, An Anomalous Case of, D. F. Cheesman, A. King and Dr. J. N. Sugden, 1099

Encyclopædia Britannica—Book of the Year 1938 (*Review*), 1120

Ends and Means: an Enquiry into the nature of Ideals and into the Methods Employed for their Realization, Aldous Huxley (*Review*), 849

Energy, transfer of, Solution of the Equation of the, and the Problem of Radiative Equilibrium, G. Tiercy, 1069

Engineering: and the New Economics, Dr. H. Chatley, 70; Services of, to Mankind, 110; Science, H. B. Brown and A. J. Bryant. Vol. 1: Mechanics and Hydrostatics (*Review*), 224; Science, Elementary, Dr. A. Morley and Dr. E. Hughes (*Review*), 224; Mechanics: Statics; Dynamics, Prof. S. Timoshenko and Prof. D. H. Young (*Review*), 461; Communication, Prof. W. L. Everitt. Second edition (*Review*), 578; Structures, The Analysis of, Prof. A. J. S. Pippard and Prof. J. F. Baker (*Review*), 578

England: The Scenery of, a Study of Harmonious Grouping in Town and Country, Dr. Vaughan Cornish. Second edition (*Review*), 142

English Physicians in France, [1838], 617

Entomologische Sammlungen, Über (ein Beitrag zur Geschichte der Entomo-Museologie) Dr. W. Horn und Ilse Kahle. Teil. 1, 2, 3 (*Review*), 348

Entomology in India, M. Afzal Husain, 338

Entomo-Museology, N. D. Riley (*Review*), 348

Entwicklungsbiologie und Ganzheit: ein beitrag zur Neugestaltung des Weltbildes, Prof. B. Dürken (*Review*), 535

Enzymes, Adaptive and Constitutive, Dr. J. H. Quastel, 41

Enzymforschung, Ergebnisse der, Herausgegeben von F. F. Nord und R. Weidenhagen. Band 7 (*Review*), 768

Epidermal Water-Content, Stomatal movement and, Prof. D. Thoday, 164

Eros, Shape of, and its Light-changes, Dr. A. C. D. Crommelin, 755

Erythroblastosis, Treatment with Ascorbic Acid of the Plasma of a Fowl affected by, Dr. E. Morelli and Dr. A. Vercellone, 202

Eskimo Origins, 87

Esperanto for Scientific Papers and Abstracts, 1007

Esters, Acidolysis of, E. Cherbuliez and Mlle. Maria Fuld, 1070

Ethical Declaration for the Times, An, L. L. Whyte, 827

Ethics: Science and, Dr. E. G. Conklin, 101; Evolution and, 110; and Ethnology, 529

Ethnographical Museums and Empire, 177; G. A. Wainwright, 332; E. Barger, 374

Ethnology, Ethics and, 529

Ethyl Dihydroxymalonate, A Reaction of, J. Parrod, 619

Eucalyptus: *astringens*, Timber of, I. Langlands, 419; Oils, The α-Phellandrene Fraction of, A. J. Birch, 761; *australiana* (Baker and Smith), Essential Oils of, and its Physiological forms, A. R. Penfold and F. R. Morrison (2), 803

Eugenic Organizations, International Federation of, Report of twelfth conference, 31

Eugenics, Medicine and, Prof. J. A. Ryle (Galton lecture), 382

Evaporation over Catchment Areas, D. Lloyd, 1063

Evolution: Quantitative, J. Small (4, 5, 6), 90; and Ethics, 110

Expeditions, The Scientific Value of, 345

Exploring as a Career, 932

Explosive Potential of a Discharge Tube without Internal Electrodes, Variations of the, under the influence of Ultra-violet or Visible Light, R. Zouckermann, 618

Extra-Galactic Systems, Two near, J. H. Reynolds, 875

Eye, Developmental Abnormalities of the, Dr. Ida Mann (*Review*), 98

Eyes, Compound, Development of, F. Bernard, 1019

Factor: Tables giving the Complete Decomposition into Prime Factors of all Numbers up to 256,000, late Dr. G. Kaván (*Review*), 454; L (Vitamin L) Requirements for Lactation in Pregnant Rats, W. Nakahara, F. Inukai and S. Ugami, 703

Fairbridge Farm Schools, Sir Hal Colebatch, 680

Fairy Shrimp, A Giant, J. E. Lynch, 693

Famine in England, Viscount Lymington (*Review*), 1036

Faraday on Electromagnetic Propagation, Sir Joseph Larmor 36

Faraday's: Experiments on Conduction, [1838], 383; Researches in Electricity, [1838], 617

Fat Metabolism, P. E. Verkade, J. van der Lee, A. J. S. van Alphen and M. Elzas (2), 1154

Fauna of British India, including Ceylon and Burma: Moths. Vol. 5: Sphingidæ, T. R. D. Bell and Lt.-Col. F. B. Scott (*Review*), 458

Faune de France, 31: Homoptères auchénorhynques, 1 (Typhlocybidæ), Prof. H. Ribaut (*Review*), 184

Faunistic and Hydrographic Changes, B. Storrow, 798

$FCBr_3$, $FCCl_3$ and, Interatomic Distances of, J. Wouters and Prof. M. de Hemptinne, 412

$FCCl_3$ and $FCBr_3$, Interatomic Distances of, J. Wouters and Prof. M. de Hemptinne, 412

Fermentation, The Intermediary Reactions of, Prof. O. Meyerhof, 855

Fermente: Hormone, Vitamine, und die Beziehungen dieser Wirkstoffe zueinander, Dr. R. Ammon und Dr. W. Dirscherl (*Review*), 896; Die, und ihre Wirkungen, Prof. C. Oppenheimer. Suppt. Lief. 7 u. 8 (*Review*), 1123

Feuerbach Quadrilateral, N. M. Gibbins, 130

Field due to two Nuclei, E. A. Hylleraas, 838

Film, The, in relation to the School Curriculum, 508

Films: for Promoting International Understanding, 29; and Folk-Lore, 441

Finsler Comet, Spectrum of the, in the Visible Region, J. Gauzit, 527

Fish: Hearing in, The Sense of, Prof. K. von Frisch, 8; who answer the Telephone: and other studies in Experimental Biology, Prof. Y. Frolov. Translated by Stephen Graham (*Review*), 393

Fisheries, British, Phosphate and the Solar Radiation Constant, Dr. W. R. G. Atkins, 77

Fishes: Sense Organs of, A. Sand, 84; Choice of Background in, F. A. Brown and D. H. Thompson, 166

Flammarion's "Annuaire Astronomique", 682

Flavin: Phosphoric Acid, Vitamin B_2 and, Karrer, Laszt and Verzár, 251; and Phosphorylated Flavin, Separation of, A. Emmerie, 416

Fleas: The Jump of, G. I. Watson, 923; British, and their Hosts, G. B. Thompson, 1062

Flights across the Atlantic, Experimental, 321

Florisbad Skull, The, Sir Arthur Keith, 1010

Flowers, British Wild, The Observer's Book of, W. J. Stokoe (*Review*), 351

Fluid Viscosity, Light Scattering and, Sir C. V. Raman and B. V. Raghavendra Rao, 242

Fluorite, Coloration and Excitation of, and a New Fluorescent Material containing Divalent Europium, Prof. K. Przibram, 1113

Fluorites, Coloured, Absorption Bands and Electron Transitions in, Prof. K. Przibram, 970

Flying Record, New, H. F. Broadbent, 783

Fœtus, Film illustrating Movement of a, Sir Joseph Barcroft and D. H. Barron, 322

Fonctionnelles, Théorie generale des, Prof. V. Volterra and Prof. J. Pérès. Tome 1 (*Review*), 1035

Food: Investigation Board, Report for 1936, 20; Values: What they are and How to Calculate them, late Margaret McKillop. Revised by Mrs. Elsie C. Mottram (*Review*), 811

Foods: Structure and Composition of, Dr. Andrew L. Winton and Dr. Kate Barber Winton. Vol. 3 (*Review*), 225; Chemistry of, [1838], 1153

Foot-and-Mouth Disease: appointment of additional members of the research committee on, 364; Carriers of, Prof. R. C. McLean, 828

Foraminifera: Life-cycle of the, E. H. Myers, 569; Modern Studies of the, Dr. W. A. Macfadyen, 750

Foreign Policy, Scientific Study of, 364

Forestry in Sweden, L. Tirén, 680

Forest Products Research Board, Report for 1936, 700

Forests: and Forestry in West Africa (*Review*), 96; Value of, 680

Formosa, Neuropteroid Insects from, N. Banks, 42

Forthcoming Books of Science, 466

Fossil: Discoveries in France, [1838], 89; Hail Impressions, Probable, in Natal Coal Measures (Middle Ecca Series), L. E. Kent, 835; Plants, Plea for a Nature Reserve of, Prof. G. R. Wieland, 324; Plankton Micro-organisms, Organic Materials forming certain, G. Deflandre, 886

Fourier Integrals, Theory of, Introduction to the, Prof. E. C. Titchmarsh; A. C. Offord (*Review*), 183

Fourth Estate, The (*Review*), 949

Fracture in Solids, Effect of the surrounding medium on, P. Rehbinder and E. Wenstrom, 1021

Frankfort Senckenburg Society of Natural Science, award of the Great Iron Medal of Honour to Prof. W. H. Hoffmann, 826

Frazer on Totemism, Prof. B. Malinowski (*Review*), 489

Free Radical of a New Type, R. Rumpf and F. Trombe, 802

French Scientific Expedition, A, [1838], 942

Freshwater Fishes, Blindness in, Dr. W. Rushton, 289

Friction, Analysis of, Nature of Sliding and the, Dr. F. P. Bowden and L. Leben, 691

Frogs: Albino, W. A. Smallcombe, 753; Heart, The Metabolism of the, Prof. A. J. Clark, M. G. Eggleton, P. Eggleton, R. Gaddie and C. P. Stewart (*Review*), 1122

Frost in England, A Severe, [1838], 131

Frozen Grounds, Principles of Mechanics of, N. A. Tsitovitch and M. J. Soumgin (*Review*), 100

'Frustration of Science' Exhibition, 966

Fucus Eggs, Ultra-centrifuged, Effect of *p*H on the development of, D. M. Whitaker, 661
Fuel: Research in Great Britain, 483; Institute of, Lt.-Col. J. H. M. Greenly appointed president of the, 683; Research Coal Survey, Dr. F. S. Sinnatt, 800; Research Station: Annual Visitation, 1064
Fuels for Heating and Hot-Water Supply, H. L. Pirie; I. Lubbock, 967
Fulham Power Station, J. F. Hay; W. C. Parker and H. Clarke, 547
Fundamental Constants, "1938-Values" of the, Prof. R. A. Millikan, 981
Fungi, Entomogenous, T. Petch, 167
Fungicides, Methods for Testing, H. B. S. Montgomery and M. H. Moore, 754
Fur Animals, Diseases of, 31
Fusarium culmorum on Wheat, G. Samuel and F. J. Greaney, 652

$GeBr_4$, Molecule, Structure of the, M. Rouault, 384
Galileo: Le Officine, Florence, Centenary of, 406; to Einstein, From, Prof. J. A. Crowther (*Review*), 891
Galloway Hydro-electric Power Development, W. Hudson and J. K. Hunter and others, 363
Game, Periodical Fluctuations in, J. Baashuus-Jessen, 477
Gamma Rays, Canalization of, Prof. F. L. Hopwood and Dr. T. E. Banks, 687
Gammarus from Ireland, Forms of, D. M. Reid, 690
Gardens of Easy Maintenance, R. S. Lynch, 71
Gas: Attacks and Defence, Major-Gen. C. H. Foulkes (*Review*), 893; Industry, Beginnings of the [1838], 1153
Gaseous: and Solid Mixtures, Reactions in, Prof. Jorissen, 420; Reactions, Some Aspects of Chemical Kinetics in, Dr. H. W. Melville, 899; Mixtures at Solid Surfaces, Adsorption of, Dr. F. J. Wilkins, 1054
Gases, Critical Phenomena in, Prof. J. E. Lennard-Jones and A. F. Devonshire, 1148
Gauss, Carl Friedrich, Inaugural Lecture on astronomy and papers on the foundation of mathematics. Translated and edited by G. W. Dunnington (*Review*), 350
Gelatine-Saponin, System, Complex Coacervation of the, B. Ruyssen and E. Verstraete, 49
Gene, Theory of the, Spontaneous Chromatin rearrangements and the, R. Goldschmidt, 385
Genes in the Chromonemata, The most probable place of location of the, Prof. D. Kostoff, 749
Genetics: and the Origin of Species, Prof. T. Dobzhansky (*Review*), 310; of Schoolboys, Dr. M. A. MacConaill, 1019; Physiological, Prof. R. Goldschmidt (*Review*), 1118; of Developmental Processes, Prof. J. B. S. Haldane (*Review*), 1119
Geodesic Postulate, A New Boundary Condition and the, Prof. V. V. Narlikar, 906
Geographical: Publications, Current, Proposed list of, 600; Exploration, [1838], 984; Society of Berlin, [1838], 1027
Geography, the Basis of Planning, Prof. P. Abercrombie and others; S. H. Beaver, 170
Geological: Society of London, award of the Wollaston medal to Prof. M. Lugeon, the Murchison medal to Dr. H. H. Bemrose, the Lyell medal to Dr. J. Pringle, the Wollaston fund to Dr. H. F. Harwood, the Murchison fund to Dr. F. C. Phillips, and moities of the Lyell fund to Dr. S. E. Hollingworth and Dr. F. M. Trotter, 150; Prof. P. Fourmarier elected a foreign correspondent of the, 1095; Excursion Guide to the Assynt District of Sutherland, Dr. M. Macgregor and Dr. J. Phemister (*Review*), 393; Faults, Major, North of Raymond Terrace and their Relation to the Structure of the Stroud-Gloucester Trough, G. D. Osborne, 803
Geology: in Great Britain: Geological Survey Publications, 696; of the U.S.S.R., Recent Developments in the, Prof. N. N. Gornostayev, 1127
Geometrical Optics, Elementary, Prof. H. S. Allen (*Review*), 136
Geometrical Isomerism in the Epoxy-Nitrile Series, R. Gerbaux, 1155
Geometries in Euclidian Space of Three Dimensions, Structure of, R. de Saussure, 1069
Geometry: Projective, An Introduction to, C. W. O'Hara and D. R. Ward (*Review*), 535; Projective, Prof. B. C. Patterson (*Review*), 811
George VI, King, Sound, 156
German: North Atlantic Expedition, 214; Meteorological Society, Prof. H. von Fischer elected an honorary member of the, 641; State Council for Research, Inauguration of the, 655; Scientific Periodicals, [1838], 659; Society of the History of Medicine, Dr. R. Kreutz awarded the Sudhoff medal of the, 1008
Ginkgo biloba (Maidenhair Tree), Origin of the name, Prof. A. C. Moule, 280
Glacial Periods, Distortion of Mountain Strata, Isostasy and, Sir Joseph Larmor, 906
Glaciers of Mount Leinster and Blackstairs Mountain, A. Farrington, 985
Glare, Effect of Veiling, on apparent Size and Distance, T. M. Martin and Dr. R. W. Pickford, 371
Glasgow: Mathematical Association, Journal of the, 782, Empire Exhibition, Science at the, 678; 860; University, Dr. J. Small elected James Watt professor of the theory and practice of heat engines; C. R. Ribbands appointed assistant in zoology, 885
Glass: Technology, Recent advances in, 154; Exhibits at the *Daily Mail* Ideal Home Exhibition, 780
Glendonites in New South Wales, with Notes on their Mode of Origin, H. G. Raggatt, 803
Gliding: and Soaring Flight, Prof. D. Brunt, 442; 712; New British Record, by J. S. Fox, 745; Flight Record, New, P. Wills, 826
Glucolytic Enzyme System, Separation of the, from the Brain Cells and its Coenzymes, A. Geiger, 373
Glycose, Identification of, M. Frèrejacque, 426
d-Glyceric Aldehyde and Tumour Glycolysis, Dr. B. Mendel, Frida Strelitz and Dorothy Mundell, 288
Glycogen Breakdown in Muscle Extract and Yeast Juice, H. Lehmann, 470
Gmelins Handbuch der anorganischen Chemie. Achte Auflage. System-Nummer 22: Kalium. Lief. 1: Element, Verbindungen bis Kalium und Sauerstoff; Lief. 2: Verbindungen bis Kalium and Chlor (*Review*), 57
Goethe medal for art and science, award of the, to Prof. G. Linck, 869; to Prof. W. Kreis, 1136
Gold Deposits of the World: with a section on Prospecting, Prof. W. H. Emmons (*Review*), 142
Golgi Apparatus, Function of, Dr. M. K. Subramaniam, 880
Goose Hybrids, E. Lonnberg, 42
Gorilla in its Home, The (*Review*), 576
Gorillas, In Quest of, Prof. W. K. Gregory and H. C. Raven (*Review*), 576
Grain, Infestation of, by Insects, Scientific Survey of, 1004
Graphite, Colloidal, An effect of X-Radiation on the ξ Potential of, I. Kemp; Prof. J. A. Crowther, 609
Grass Seed Production, Bulletins on, 639
Gravity, Measurements of, in the South of China, P. Lejay and Chang Hung Chi, 844
Graz University, Prof. E. Schrodinger and, 929
Great: Salt Lake Region, Ancient Caves of the, J. H. Steward, 44; Britain, Geographical and Economic Survey of (*Review*), 767; Barrier Reef, Wonders of the, T. C. Roughley (*Review*), 811; Britain and France, Co-operation between, 868; Arid Filter, Through the (Man's Drift to Europe), A. J. McInerny (*Review*), 1122
Greek: Cosmogony and Astronomy, Dr. K. Lundmark, 29; Wolf Lore, Dr. R. P. Eckels, 693
Green Flash from Venus, Capt. W. G. West and W. G. Burt, 168
Greenland, North-West, and the Canadian Arctic, An Expedition to, J. M. Wordie, 931
Green's Function for an Ellipse and its application to the Motion of a Point Vortex, D. Meksyn, 986
Greenwich: Lunar Observations, [1838], 984; Royal Observatory, Annual Visitation, 1065

Gregory, Olinthus, retirement of, [1838], 1112
Grey Squirrel in Britain, Spread of, A. D. Middleton and B. T. Parsons, 519
Growth-Promoting Substances: Absorption of, by Cuttings, T. H. Jackson, 835; in Horticultural Practice, Dr. M. A. H. Tincker, 1147
Gypsies: Serbian, Holy Days among, Dr. A. Petrović, 208; Albanian, Mrs. Margaret Hasluck, 979
Gypsum and Anhydrite, A. E. Hill, 85

Hadrian's Wall, I. A. Richmond, 505
Hæmoglobin, Chymotrypsin and, An X-Ray study of, Prof. J. D. Bernal, Dr. I. Fankuchen and M. Perutz, 523
Haffkine Institute, Bombay, Report for 1936, 782
Haifa, Hebrew Technical Institute, 1083
Hailstones, Large, Formation of, T. E. W. Schumann, 126
Halicystis, Potentials in, as affected by Non-Electrolytes, W. J. V. Osterhout, 661
Halteres of Flies as Gyroscopic Organs of Equilibrium, G. Fraenkel and J. W. S. Pringle, 919
Hamburg Hanseatic University, Sir Aldo Castellani elected an honorary member of the, 1052
Hancock's Steam Gig, [1838], 801
Harper Adams Agricultural College, Review of its Advisory work, 113
Harper and Joyce's Heating Stove, [1838], 701
Haslemere Educational Museum, Fiftieth Anniversary, 1091
Health: Services of Great Britain (*Review*), 624; Progress: Twenty-five Years of, a Study of the Mortality Experience among the Industrial Policy-holders of the Metropolitan Life Insurance Company, 1911 to 1935, Dr. L. I. Dublin and Dr. A. J. Lotka (*Review*), 953
Hearing in Fish, The Sense of, Prof. K. von Frisch, 8
Heart: Clinical Studies of the (*Review*), 533; Diseases of the, described for Practitioners and Students, Sir Thomas Lewis. Second edition (*Review*), 533
Heat: Production, Nutrition and Growth in Man: Some New Views, Dr. E. P. Poulton, 145; 187; Evolved in the Internal Transformation of a Block of Lead produced by the action of its Own Weight, Study of the quantity of, W. Swietosławski, L. Keffler and J. Salcewicz, 344; Loss from the Human Body: Physical Laws of, J. D. Hardy, 385; Regulation of, J. D. Hardy and E. F. Du Bois, 385
Heavy Elementary Particles, Structure of, Prof. G. Beck, 609
Hebrew Technical Institute, Haifa, 1083
Hedgehog Serum, Magnesium and Calcium Content of, during Hibernation, Dr. P. Suomalainen, 471
Helium: Liquid, Viscosity of, below the λ-point, Dr. P. Kapitza, 74; II, Liquid, Flow of, J. F. Allen and A. D. Misener, 75; II, New phenomena connected with Heat Flow in, J. F. Allen and H. Jones, 243; Ionized, Relativistic Stark Effect of, Dr. B. Kullenberg, 244; formed in Beryllium, Identification and Measurement of, by Gamma Rays, E. Gluckauf and F. A. Paneth, 259; in Beryls, Occurrence of, J. W. J. Fay, E. Glückauf and F. A. Paneth, 259; Liquid, The λ-phenomenon of, and the Bose-Einstein Degeneracy, Dr. F. London, 643; II on Glass, Transfer of, J. G. Daunt and Dr. K. Mendelssohn, 911; II, Liquid, Experiments with, A. K. Kikoin and B. G. Lasarew, 912; II, Transport Phenomena in, Dr. L. Tisza, 913; Liquid, Velocity of Sound in, Prof. E. F. Burton, 970
Helix pomatia: Descent of the Ovocytes in, J. L. Perrot, 427; Diffusion of Acetylcholine starting with the Heart of, M. Bouchet, A. Jullien, D. Vincent and Mlle. Madeleine Vuillet, 661
Henry's Investigations on Electrical Induction, [1838], 801
Herbert, William, and Amaryllis Culture, 884
Herbivora, Gastro-Intestinal Tract of, Disintegration of Cell-wall Substances in the, F. Baker and R. Martin, 877
Heredity of Acquired Characters, L. Daniel, 943
Herring, Food of the, 257
Herschel, Sir John, Dinner to, [1838], 1068
Hessian Fly, A Parasite of the, C. C. Hill and W. T. Emery, 167
Heterochromatin at the Distal Ends of the Chromosomes in *Triticum monococcum*, Prof. D. Kostoff, 690
Heterotrophic Cells, Metabolism of, Function of Carbon Dioxide in the, Dr. J. W. Hes, 647
High-Voltage Insulation, Limitations of, Dr. Whitehead, 86
Himalaya, Structure of the, and of the North Indian Foreland, D. N. Wadia, 296
Hindukush Tribes, Racial Composition of the, Dr. B. S. Guha, 339
Histamine and the Action of the Thyroid Gland, Dr. F. Ellinger, 1014
Hittites in Northern Syria, Sir Leonard Woolley, 1092
Holland, Museums of, Work of the, J. de La Valette, 177
Homoptera, Permian, and Psocoptera, Structure of, Dr. F. M. Carpenter, 164
Hooke's Experiments on Combustion, Dr. D. J. Lysaght, 323
Hooker's "Icones Plantarum", [1838], 48
Hopkins, Sir Frederick Gowland (Scientific Worthies XLVIII), Prof. H. Wieland, 989
Hormones: administered, Effectiveness of, Drs. Deanesly and Parkes, 292; Gonad-stimulating, Standardization of, P. G. Marshall, 605; Ovotrophic and Folliculoplasic, Dr. J. Freud, 1013
Hornbills, Curious Breeding Habits of, R. E. Moreau, 477
Horse Serum Pseudoglobulin, Normal, Enzymatic removal of bound Carbohydrate from, A. G. Ogston, 1056
Hottentots, Bushmen and, Prof. H. R. Drennan, 1146
Housing, Noise and, 758
Human: Behavior: Factors Determining (*Review*), 448; Studies in (*Review*), 448; Conflict: The Biology of, an Anatomy of Behaviour, Individual and Social, Dr. T. Burrow (*Review*), 462; Situation, The, Prof. W. M. Dixon (Gifford lectures, 1935–1937) (*Review*), 463; Temperature in Different Climates, [1838], 659; Intellect, Obsessions and Convictions of the, F. W. Westaway (*Review*), 766; Heredity, Bureau of, Appeal for Funds, 1091
von Humboldt, A letter from, [1838], 299
Hunter, John, as a Pioneer of Veterinary Science, Sir Frederick Hobday, 521
Huygens, Christiaan, Œuvres complètes de, Tome 19: Mecanique théorique et physique de 1666 à 1695 (*Review*), 665
Hydrobiology and Fisheries Laboratory, Alexandria, Hussein Faouzi, 1107
Hydrocarbons: Ozonation of some (Hexane, Heptane and various Octanes), E. Briner, C. El-Djabri and H. Paillard, 485; Dr. E. F. Armstrong (*Review*), 492; Pure, The Reactions of, G. Egloff (*Review*), 492
Hydrogen: Peroxide, Mechanism of the Decomposition of, by Catalase, D. Keilin and E. F. Hartree, 216; and Chlorine, Photochemical Union of, Prof. A. J. Allmand, H. C. Craggs and G. V. V. Squire, 253; Reactions of, with Organic Compounds over Copper-Chromium Oxide and Nickel Catalysts, Prof. H. Adkins (*Review*), 811; Atom, Surround of an, by an infinitely High and Steep Spherical Potential wall, Prof. A. Sommerfeld and H. Welker, 981; Molecules, Long-range Forces between, H. S. W. Massey and R. A. Buckingham, 1112
Hydrographic Changes, Faunistic and, B. Storrow, 798
Hydroxides and their Applications, Prof. N. R. Dhar (*Review*), 6
Hymenopterous Insects, Genitalia of, O. Peck, 293
Hydroxyde und Oxyhydrate, Prof. F. Fricke und Prof. G. F. Hüttig (*Review*), 6
Hydroxyl Frequency in Carboxylic Acids, M. M. Davies and Dr. G. B. B. M. Sutherland, 372
Hypochlorite and Hypobromite Reactions, Kinetics of the, A. and R. Skrabal, 703
Hypophysis, Biochemistry of the Antipathic Substances in the Anterior and Posterior Lobes of the, H. Przibram, 1113

Ice: Accretion on Aircraft, Sir George C. Simpson, 167; in Finnish Waters, Dr. R. Jurva, 478; Ages, Sir George Simpson, 588, 591; and Fire, Land of, Prof. H. W. Ahlmann (*Review*), 896

Iceland: Woodlice of, 478; Zoology of, 611

Igneous Rocks, The Petrology of the, late Dr. F. H. Hatch and Dr. A. K. Wells. Ninth edition (*Review*), 952

Illumination of Buildings, Prof. J. O. Kraehenbuehl, 43

Image Micrometer, A Comparison, C. R. Davidson and L. S. T. Symms, 695

Immortality: Horizons of, A Quest for Reality, Baron Erik Palmstierna (*Review*), 994

Impact Stresses in a Freely Supported Beam, R. N. Arnold, 653

Imperial: Unity, The British Association and, 93; Leopold Caroline Germany Academy of Halle, Dr. E. Richters elected a member of the, 550; new nominations for membership of the, 601; College of Tropical Agriculture, Sir David Prain appointed life-president of the, 745

Impulse Voltages, Effects of, on Transformer Windings, Dr. T. E. Allibone, D. B. Mackenzie and F. R. Perry, 45

Incunabula Scientifica et Medica, A. C. Klebs, 600

India: Biochemistry in, 31; Rabies Prevention in, Dr. R. O. A. Smith, 72; The Scientific Delegation in, 107; British, including Ceylon and Burma, The Fauna of, Protozoa: Ciliophora, Dr. B. L. Bhatia (*Review*), 142; Scientific: Delegation to, 193; Research in, 230; National Institute of Sciences of, election of officers, 282; Science in, Sir John Russell, 295; 338; Zoology and its Advancement in, Prof. G. Matthai, 338; Radio Research in, 364; Science in, 379; the Scientific Delegation to, 440; Culture-Contact in (*Review*), 450; Butterflies of, A Guide to Collecting, Lt.-Col. H. D. Peile (*Review*), 458; Veterinary Work in, Development of, Sir Arthur Olver, 480; Microlithic Industries of, Col. D. H. Gordon, 519; Irrigation of Dry Hill Sal Areas in, W. P. M. Warren, 565; The Rivers of, 797; Race and Language in, Dr. D. N. Majumdar, 1019; Archæological Research in, Sir Leonard Woolley to advise on, 1131

Indian: Science Congress, Jubilee Meeting of the, 1; Sir James Jeans's presidential address, 68; 151; Universities and Nationalism, 155; Villages, Education in the, Capt. J. W. Petavel, 639; Brackish Water Fauna, N. K. Panikkar and R. G. Aiyar, 652; Cultural Studies, 743; Rivers: Problem of, Prof. M. N. Saha, 797; Geological History of, D. N. Wadia, 980

Indium Hydride, Band Spectrum of, Dr. B. Grundström, 555

3-Indol-Acetic Acid, Formation of, by the Action of Ultra-Violet Radiation on Tryptophane, A. Berthelot and Mlle. Germaine Amoureux, 802

Induction Experiment, An Unsuccessful, [1838], 1068

Industrial: Accidents and Sickness, Prof. M. Greenwood and others, 613; Selection, Psychological Tests in, Sir Frederick Marquis and others, 613

Industry, Science and, Sir Richard Gregory, Bt., 799

Influenza: Research on, Report on, 779; Institute established at Budapest, 826

Injection Motors, Working of, and Igniting by Compression in a Rarefied Atmosphere, P. Clerget and R. Marchal, 660

Inland Lakes, Abnormal Thermal Stratifications of, S. Yoshimura, 175

Insect Survival, Activity and, Dr. K. Mellanby, 554

Insecticides: Mineral Oils as, J. Carroll, 568; Methods for Testing, W. Steer, 754

Insects: Affecting Stored Products, H. Hayhurst, 124; of the British Woodlands, Dr. R. N. Chrystal (*Review*), 226; Aerial Drift of, Prof. A. C. Hardy and P. S. Milne, 602; Nematodes and, Association between, P. Bovien, 758; 'Climbing Organs' in, Dr. V. B. Wigglesworth, 974; Control of, by Methallyl Chloride, C. J. Briejèr, 1099

Institute: of Chemistry, presentation of the Meldola medal to R. P. Bell; award of the Sir Edward Frankland medal and prize to L. Smith, 469; of Metals medal, award of the, to Sir William Bragg, 469; of Medical Chemistry, at Keio, Japan, Inauguration of an, 1136

Insulation: High-Voltage, Limitations of, Dr. Whitehead, 86; Plastics and, L. Hartshorn, N. J. L. Megson and E. Rushton, 599

Insulin in Cell-free Extracts, Action of, H. Lehmann, 690

Integral Equations, Theory of (*Review*), 1035

Integration: Modern Theories of, H. Kestelman (*Review*), 455; Theories of, Developments in (*Review*), 455

Intellectual Work, Mental Hygiene of, Dr. C. S. Myers, 477

Intensities, Law for Minimal Discrimination of, W. J. Crozier and A. H. Holway (3), 1071

Intermetallic Compounds in the Molten State, Stability of, Dr. E. Heymann and H. P. Weber, 1059

International: Commission of Radiologists and Roentgenologists, award of the Carlos Heiser medal to Prof. H. Wintz, 73; Relations, Psychology of, Dr. W. Brown, 152; Telecommunications Conference at Cairo, 195; Economic Collaboration, M. Van Zeeland, 236; Aeronautical Federation, award of the gold medal of the, to Miss Jean Batten, 241; Institute Examinations Enquiry: a Conspectus of Examinations in Great Britain and Northern Ireland, Sir Philip Hartog, with the assistance of Grace Roberts (*Review*), 463; Radiological Units and Protection Congress, Dr. Holthusen elected president of the, 498; Co-operation, Promotion of, 506; Affairs, Scientific Research in, 947; Ornithological Congress, Ninth, 1003; Committee for Bird Preservation, 1003; J. Delacour elected president, 1004; Conference for the Protection of the Fauna and Flora of Africa, 1024

Interstellar Matter as the Eventual Cause of the Displacement of the Spectrum of Nebulæ towards the Red, L. Schames, 485

Invention, Social Imports of, 261

Iodine: Prof. Irvine Masson, 227; Educational Bureau, Dr. F. C. Kelly appointed director of the, 1049

Ion Emission, Positive, from Heated Nickel Wire in Oxygen and Hydrogen, R. Goto, 175

Ionization and Conductivity in Gases at High Pressures, J. Clay, 384

Ionized Air, Refractive Index and Conductivity of, Effect of Longitudinal Magnetic Field on the, Dr. S. S. Banerjee and B. N. Singh, 511

Ionosphere: Earth's Magnetic Field in the, the Lorentz Polarization Term and the, Dr. D. F. Martyn and G. H. Munro, 159; Medium Radio Waves in the, Magnetic Double Refraction of, Prof. E. V. Appleton, Dr. F. T. Farmer and J. A. Ratcliffe, 409; *E* Region of the, Meteoric Ionization in the, Prof. A. M. Skellett, 472; Constitution of the, and the Lorentz Polarization Correction, H. G. Booker and L. V. Berkner, 562

Ireland: Mammals of, C. B. Moffat, 837; Archæological Studies in, 1031; North-East, Glacial Geology of, Prof J. K. Charlesworth, 1112

Irish Archæology, New Aspects and Problems in, Dr. A. Mahr, 1041

Iron: Wire, Magnetic Quality of, as Influenced by the Diameter, Dr. T. F. Wall, 205; and Steel Institute, award of the Bessemer gold medal to Dr. C. H. Desch, 469; Active, Preparation of an, and its Application to the Semi-hydrogenation of Acetylene Derivatives, R. Paul and G. Hilly, 761; Smelting, Prehistoric and Primitive, E. W. Hulme, 824; Wire, Magnetic Quality of, Effect of Manganese Coating on the, Dr. T. F. Wall, 1016

Irrigation: in Egypt, 298; of Dry Hill Sal Areas in India, W. P. M. Warren, 565

Isle of Man, Marine Fauna of the, Dr. H. B. Moore, 508

Isocholesterol and Isomeric Ethers of Cholesterol, E. S. Wallis, E. Fernholz and F. T. Gephardt and others, 478

Isomerism, A Novel Type of, in a Co-ordination Compound of Copper, D. P. Mellor, G. J. Burrows and B. S. Morris, 414

Isoprene, Butadiene and Chloroprene at Low Temperature X-Ray Study of, Dr. C. J. B. Clews, 513
Isopropanol in Alcohols, Detection of Small Quantities of, M. Métra, L. Lesage and F. Descatoire, 986
Isotope ^{5}He, Formation of an, During Collisions between Helions and Deuterons, F. Joliot and I. Zlotowski, 1113
Isostasy: Final, Distorted Mountain Strata in Relation to, Sir Joseph Larmor, 603; Distortion of Mountain Strata, and Glacial Periods, Sir Joseph Larmor, 906

Japanese Nationalism and Intellectual Freedom, 781
Javanese Culture, Survivals and Reversions in, Dr. F. Stutterheim, 754
"Jewish" Spirit in Science, The, 778
Journal: *of Comparative Pathology and Therapeutics*, Jubilee No. and *Festschrift*, 1003; *of Pomology and Horticultural Science*, Enlargement of Scope of the, 1051
Jupiter: South Equatorial Current of, A. Stanley Williams, 1063; Markings of the Third Satellite of, in Transit Across the Planet, Dr. E. M. Antoniadi, 1106

K-Electron Capture, Nuclear Transformation by, Dr. E. J. Williams and E. Pickup, 199
Kaiser Leopold Caroline German Academy of Natural Science, Halle, Prof. H. Burger nominated a member of the, 325
Kala-Azar and Malaria, Sir U. Brahmachari, 379
Karrer's Theory of Coupling, Dr. W. J. Hickinbottom and E. W. Lambert, 1056
Kelland, Philip, appointed to Edinburgh, [1838], 1111
Kelsey Plums, Ripening of, Effect of Acetylene on the, V. A. Putterill, 875
Kelvin medal, award of the, to Sir J. J. Thomson, 408; 683; presentation of the, to Sir J. J. Thomson, 825; address by Lord Rayleigh, 883
Kepler: Newton and Bode, Prof. G. W. Todd, 412; Johannes, Gesammelte Werke. Band 3. Astronomia Nova. Herausgegeben von M. Caspar (*Review*), 665
Keratin Molecule, Constitution of the, Dr. J. B. Speakman and E. Stott, 414
Ketones and Secondary Alcohols, Photochemical Interaction between, C. Weizmann, Y. Hirshberg and Dr. E. Bergmann, 1012
King's: College, London, Prof. G. M. Bennett appointed professor of chemistry, 403; birthday honours list, 1088
Knight, Thomas Andrew (1759–1838), 843
Knossos and Ras Shamra, Vaulted Tombs of, Sir Arthur Evans, 124
Knowledge: and World Progress, Prof. A. Ferguson (*Review*), 707; Unified, Service of, 1133
Kola Peninsula, Apatite, Nepheline, and Rare-Earth Mining in the, Dr. G. W. Tyrrell, 354
Kramer's Absorption Law in Astrophysical Problems, T. L. Page, 1137
Kristalle: Schwingende, und ihre Anwendung in der Hochfrequenz und Ultraschalltechnik, Prof. L. Bergman (*Review*), 535
Kürten: Peter, A Study in Sadism, G. Godwin (*Review*), 997
Kurumi (Japan) Meteorite, The, F. Watson, jun., 475

Lachish, Early Hebrew Script at, 1004
Lactoflavin in the Eyes of Fish, E. Adler and Prof. H. v. Euler, 790
Lake Biwa, Crustal Deformations Around, Prof. C. Tsuboi, 337
Lamellibranch Molluscs, Degradation of Substances of Puric Origin in the, A. Brunel, 886
Land Mammals of the Western Hemisphere, A History of, Prof. W. B. Scott. Revised edition (*Review*), 894
Landscape at the Royal Academy, L. C. W. Bonacina, 818
Lantern Adaptor for Film Strips, 795
Laue Diagrams, Twenty-fifth anniversary of, 600
Latitude Variations in 1936 and 1937, R. Schumann, 1113
Lava, Submarine Coulées of, in the Flysch of the Sheet of la Brèche, Discovery of, W. J. Schroeder, 945
Lavoisier, Traité élémentaire de chimie de (*Review*), 954
Lead: Ordinary and Uranium-Isotopic Composition of, J. Mattauch and V. Hauk, 43; Supraconductive, Thomson Effect of, Dr. J. G. Daunt and Dr. K. Mendelssohn, 116; Higher Oxides of, G. L. Clark, N. C. Schieltz and T. T. Quirke, 126
League of Nations: award of the Darling prize of the, to Prof. N. H. Swellengrebel, 198; Health Committee of the, Report of the, 280; Medical Mission to the Far East Respecting Epidemics, 509; Non-Political Value of the, Capt. A. L. Kennedy, 637
Leakey, Mr., My Friend, Prof. J. B. S. Haldane (*Review*), 7
Learned Professions, Unemployment in the: W. M. Kotschnig, 51; An International Study of Occupational and Educational Planning, Prof. W. M. Kotschnig (*Review*), 303
Leaves, Protein Content of, Factors Affecting, A. H. K. Petrie and J. G. Wood, 478
Leeds: College of Technology, Work of the, 240; University: Dr. G. Holmes appointed honorary lecturer in medical hydrology and C. Ludwig a demonstrator in physiology, 216; W. E. Adams appointed lecturer in histology, 567; C. L. Bird appointed lecturer in dyeing, 618; Report for 1936–37, 639; Prof. Mouat Jones appointed vice-chancellor, 801; Dr. D. T. A. Townend appointed Livesey professor of coal gas and fuel industries, 964; 985
Leibniz: A Critical Exposition of the Philosophy of, with an Appendix of Leading Passages, Bertrand Russell (*Review*), 464
Length: and Weight, National Standards of, [1838], 843; $r_0 = e^2/mc^2 = 2{\cdot}81 \times 10^{-13}$cm., Relevancy of the, Prof. W. Heisenberg, 981
Leopold II, Order of, conferment upon Prof. H. S. Taylor of the Cross of Commander of the, 241
Lepidoptera: Feeding Mechanism of, J. B. Schmitt, 419; Metabolism in, I. W. Kozhautshikov, 1105
Leuconostoc dextranicum, The Polysaccharide Produced from Sucrose by, Dr. S. Peat, Dr. M. Stacey and E. Schlüchterer, 876
Leyden University Botanical Gardens, 350th Anniversary of the, 365
Lichens from Greenland, B. Lynge, 336
Life: and Death: the Autobiography of a Surgeon, Prof. A. Majocchi. Translated by H. J. Stenning (*Review*), 267; and Work, Out of My, Prof. A. Forel. Translated by B. Miall (*Review*), 267; as a Whole, Dr. J. W. Bews (*Review*), 853
Light: Diffraction of, by Supersonic Waves in Solids, N. S. Nagendra Nath and Prof. H. Mueller, 37; A Textbook of, L. R. Middleton. Second edition (*Review*), 136; G. R. Noakes (*Review*), 136; V. T. Saunders. Third edition (*Review*), 136; Scattering and Fluid Viscosity, Sir C. V. Raman and B. V. Raghavendra Rao, 242; Principles and Experiments, Prof. G. S. Mohk (*Review*), 669; Convergent Beams of, Illusion of, Dr. A. H. Rosenthal, 836; 1060; G. Colange and Dr. Y. Le Grand, 1059; Measurements, Submarine, H. H. Poole and others, 1152
Lighting: Public, Centralized Control of, H. P. Barker, 934; Street, Correct, 1092
Lightning: Photography of, in Daytime, Dr. B. F. J. Schonland, 115; Strokes, Sir Joseph Larmor, 115; Discharge, The, Dr. B. F. J. Schonland, 520
Lignifying Cells, The Oxidation-Reduction Potential in, K. Griffioen, 876
Lily, The Day, G. P. Baker, 549
Limnæa peregra, Dextrality of, Capt. C. Diver and I. Andersson-Kotto, 1020
Limnology of Two Lakes on the Oceanic Island, Kita-Daitō-Zima, S. Yoshimura, 703
Lincei, National Academy of the, awards of the, 641
Linnæan Tradition, The, 959

Linnæus: The "Critica Botanica" of. Translated by the late Sir Arthur Hort. Revised by Miss M. L. Green (*Review*), 993; and the Species Concept, Dr. J. Ramsbottom, 998

Linnean Society of London: Publications of the, 111; award of the Linnean gold medal to Sir D'Arcy W. Thompson, 745; A History of the, Lt.-Col. A. T. Gage (*Review*), 895; election of officers, 969; presentation of the Linnean gold medal to Sir D'Arcy W. Thompson, 1002

Lipin Phosphorus in Normal and Rachitic Rats, Formation of, with a Radioactive Phosphorus Isotope as an Indicator, Dr. M. J. L. Dols, Prof. B. C. P. Jansen, Prof. G. J. Sizoo and F. Barendregt, 77

Lipoid Films, Complex Formation in, Dr. J. H. Schulman, E. Stenhagen and Prof. E. K. Rideal, 785

Liquids: Double Refraction of, New Properties of, Submitted to Ultra-Sounds, R. Lucas, 886; Theory of, Dr. T. S. Wheeler, 937; Some Dispersive, G. Ahier, 944

Lister Institute, Elstree, Fire at the, 365

Live and Learn We: Addresses on Education, Sir Josiah Stamp (*Review*), 462

Liverpool: University, Dr. R. M. Gordon appointed Dutton memorial professor of entomology, 618; and Manchester Railway, Locomotives on the, [1838], 215

Livestock Improvement, Acclimatization in Relation to, Prof. R. Prawochenski, 922

L.M.S. Rly.: Dr. W. A. Macfarlane appointed senior research chemist to the, 550; A. S. Davison awarded the Herbert Jackson medal and prize of the, 930

Locke, John, Prof. R. I. Aaron (*Review*), 1080

Locust Outbreaks in Africa and Western Asia, Dr. B. P. Uvarov and Miss W. Milnthorpe, 443

Lodge, Prof. Alfred, E. A. G., 290

Log π and other Basic Constants, H. S. Uhler, 569

Logic, Science, Philosophy and, Dr. H. Jeffreys, 672; 716; 977;

London: and Southampton Railway, [1838], 843; School of Economics, 277; School of Hygiene and Tropical Medicine, Report for 1936–37, 238; Lt.-Col. H. E. Shortt appointed reader in medical parasitology at the, 660; University: conferment of title of reader in entomology on Dr. O. W. Richards; conferment of doctorates on S. J. Madge, F. T. Bennett and C. E. Wynn-Williams, 258; Prof. G. M. Bennett appointed professor of chemistry at King's College, R. S. Pilcher professor of surgery at University College Hospital Medical School, E. R. Bolton and Lt.-Col. R. D. T. Alexander fellows of King's College, Dr. E. J. Allen, Dr. H. L. Eason, Prof. E. Mapother, A. S. Quartermaine, C. C. Walker, C. S. White and J. A. Wilks fellows of University College; conferment of title of professor emeritus on Prof. A. E. Boycott, 426; Imperial College of Science and Technology, Prof. I. M. Heilbron appointed professor of organic chemistry, 504, 525; W. J. John appointed professor of electrical engineering at Queen Mary College, 525; Dr. F. R. Winton appointed professor of pharmacology at University College and Dr. R. V. Christie professor of medicine at St. Bartholomew's Hospital Medical College, 618; conferment of doctorates on Miss D. R. Crofts and W. B. Pollard, 801; Report of Dr. H. L. Eason for 1937–38; Archæology in, 967; Prof. H. H. Read appointed professor of geology at the Imperial College of Science and Technology; Dr. G. R. de Beer appointed reader in embryology at University College; conferment of title of professor on Dr. H. Dingle; award of Dunn exhibitions to S. D. V. Weller and J. W. L. Doust, 985; Television Service, T. C. Macnamara and D. C. Birkinshaw, 1108; University College, Annual Report, 1134; Mathematical Society, award of the De Morgan medal to Prof. J. E. Littlewood, 1136

London's Water Supply, Safeguarding, Lt.-Col. Harold, 866

Long's Liniment, St. John, [1838], 1068

Lorentz Polarization: Term, The, and the Earth's Magnetic Field in the Ionosphere, Dr. D. F. Martyn and G. H. Munro, 159; Correction, Constitution of the Ionosphere and the, H. G. Booker and L. V. Berkner, 562

Lower Carboniferous Flora of Berwickshire, Some Undescribed Species from the, Mary G. Calder, 343

Lowe's, James, Screw Propeller, [1838], 526

Lucretius: De Rerum Natura. Translated by R. C. Trevelyan (*Review*), 346; F. S. Marvin (*Review*), 346; Poet and Philosopher, E. E. Sikes (*Review*), 346

Luminescence Research, Industrial, A. Van Wijk, 694

Lutecium, Atomic Weight of, Hönigschmid, 42

Lycopene, Spontaneous Isomerization of, L. Zechmeister and P. Tuzson, 249

Lymphogranuloma Inguinale (Climatic Bubo), Developmental Forms of the Virus of, Dr. G. M. Findlay, R. D. Mackenzie and F. O. MacCallum, 877

Madras Plankton, Decapod Larvæ from the, M. Krishna Menon, 208

Madrid Astronomical Observatory, Anuario of, 682

Magmas, Origins of, R. W. van Bemmelen, 653

Magnetic: Storm of April 16, 721; Dr. A. H. R. Goldie, 722; Storms, Recent Solar Eruptions, Auroras, and, A. J. Higgs and R. G. Giovanelli, 746; Storm of April 16, 779; Permeabilities, Higher, R. M. Bozorth, 796; Observations at Greenwich, [1838], 942

Magnesium and its Alloys, Dr. J. L. Haughton and W. E. Prytherch, 45

Magnetism: Relating to Chemistry, Prof. S. S. Bhatnagar, 296; at Low Temperatures, [1838], 942

Magnets, Permanent, Effect of Temperature on, A. C. Whiffen, 168

Maiden Castle, Dorchester, Closing Excavations at, Dr. R. E. Mortimer Wheeler, 404

Malaya: A Jungle Tribe of (*Review*), 449; The Negritos of, I. H. N. Evans (*Review*), 449

Malvern College, New Science Block at, 1049

Malnutrition and Maternal Mortality, Lady Williams, 257

Mammals, Extinct, of the Western Hemisphere (*Review*), 894

Management: Modern, Prof. J. E. Walters (*Review*), 393; Library, Progress of the, 444

Manam, New Guinea, Woman's Status in, Miss Camilla H. Wedgwood, 837

Manchester University: Dr. W. Jackson appointed Edward Stocks Massey professor of electrotechnics, and director of the electro-technical laboratories, 504; 525; Dr. A. R. Todd appointed Sir Samuel Hall professor of chemistry and director of the chemical laboratories, 1130; 1153

Manchu Soybean, Light Intensity and the Nitrogen Hunger Period in the, E. B. Fred, P. W. Wilson and O. Wyss, 569

Mandæans: The, G. R. Driver (*Review*), 765; of Iraq and Iran: The, Their Cults, Customs, Magic, Legends and Folklore, Mrs. E. S. Drower ('E. S. Stevens') (*Review*), 765

Manganese: Cobalt and, Stereochemistry of, E. G. Cox, A. J. Shorter, W. Wardlaw and W. J. R. Way, 126; in the Biological Synthesis of Ascorbic Acid, Role of, M. N. Rudra, 203

Man's Relations to Nature and his Response, Sir P. Chalmers Mitchell and others, 589

Manure Industry, An Unexpected Intervention of the, in Reducing the Fertility of Soils, G. Bertrand, 526

Mapungubwe: Ancient Bantu Civilization on the Limpopo. Edited by L. Fouché (*Review*), 222

Marine: Egg Membranes, Electric Impedance of, Dr. K. S. Cole, 79; Biology, Bequests for Research in, E. T. Browne, 636; Plankton Animals as Indicators of Water Movements, J. H. Fraser, 837; *Research, Journal of*, 548

Marsupials, Classification of, A. A. Abbie, 42

Martensite, Orientation Habit of, A. B. Greninger and A. R. Troiano, 38

Materials and their Testing, Joint Committee on, 1005

Maternal Mortality, Malnutrition and, Lady Williams, 257

Mathematical: Teaching, Relevance of Mathematical Philosophy to, M. Black, 130; Association: Annual Meeting; W. Hope-Jones elected president, 129; Probability, Introduction to, Prof. J. V. Uspensky (*Review*), 769

Mathematics: Pure and Applied, Relative Value of, Dr. W. G. Bickley and others, 130; for the Million, Prof. L. Hogben. Second edition (*Review*), 388; for Technical Students (*Review*), 668; Operational, The Elementary Theory of, Prof. E. Stephens (*Review*), 668; Practical, Studies in, A. C. Aitken (3), 760

Mathematik, Höhere, fur den Praktiker, H. A. Lorentz. Neu bearbeitet von Prof. G. Joos und Prof. T. Kaluza (*Review*), 1038

Mathematische Keilschrift-Texte, Herausgegeben und bearbeitet von O. Neugebauer. Teil 3: Ergänzungsheft (*Review*), 5

Matter: Transmutation of, late Lord Rutherford, 58; Properties of, D. N. Shorthouse. Revised edition (*Review*), 465; Properties of, in Modern Guise, F. Ian G. Rawlins (*Review*), 810

Mauritius: Shells of, R. Viader, 478; Plants, R. E. Vaughan, 682; Cyclone Season 1934–35 at, M. Herchenroder, 1020

Maxwell's Equations: A Simplification of, in Conformity with the Flux-cutting Principle, Dr. C. V. Drysdale, 254; and the "Flux-Cutting" Principle, Dr. J. A. Wilcken; Dr. C. V. Drysdale, 907

May the Twelfth Mass Observation Day Surveys 1937. Edited by H. Jennings and others (*Review*), 448

Mechanical Engineers, Institution of, award of the James Watt international gold medal to Henry Ford, 778

Mechanics and Hydrostatics, Further, A. W. Siddons, K. S. Snell and N. R. C. Dockeray (*Review*), 224

Medical: Practice, The Physiological Basis of, Prof. C. H. Best and Prof. N. B. Taylor (*Review*), 57; Research in Canada, 365; Milestones, 549; Missions, [1838], 617; Research in Canada: Medical Research Committee, 656; Biography, [1838], 701; Inventions and Discoveries, 705; Research: Council: Report for 1936–37, 705; Report for year 1936–37, 957; in Great Britain, 957

Medicine: as a State Service, Sir George Newman (*Review*), 3; Socialised, in the Soviet Union, Dr. H. E. Sigerist (*Review*), 3; Physical, Association for, Aims of the, 282; and Eugenics Prof. J. A. Ryle (Galton lecture), 382; The Romance of, Dr. J. A. Hayward (*Review*), 461

Medieval Mummy, [1838], 701

Melanesia, Africa and, in Transition, Prof. R. Thurnwald 1061

Melbourne University, Dr. J. S. Turner appointed professor of botany, 504; 525

Mental: Factors, Methods of Estimating, Prof. G. H. Thomson, 246; Defect: A Clinical and Genetic Study of 1280 Cases of, Dr. L. S. Penrose (*Review*), 575; Prof. J. B. S. Haldane (*Review*), 575; Factors: Methods of Estimating, Dr. M. S. Bartlett, 609; A Shortened Method of Estimation of, by Regression, Dr. W. Ledermann, 650

Mercuric Oxide, Allotropy of, A. B. Garrett and A. E. Hirschler, 479

Mercurous Chloride, Action of Ammonia on, H. R. Frecke and M. C. Sneed, 937

Mercury: Double Iodides, Magnetic Properties of the, F. Gallais, 132; Vapour, Toxicity of, to Insects, H. C. Gough, 922; Benedicks Effects in, Effects of Gas Ions on the, Prof. C. Benedicks and P. Sederholm, 1097

Mersey, River, Estuary of the, Effect of the Discharge of Crude Sewage into the Estuary of the River Mersey on the Amount and Hardness of the Deposit in the Estuary, 1081

Mesolithic Flints from West Hartlepool, Dr. C. T. Trechmann, 335

Mesomeric Systems, Formation of, Prof. J. Kenner, 786

Mesomerism, Resonance and, Prof. C. K. Ingold, 314

Mesophyll of the Leaf, Nature of the Outer Surface of the Cell Walls of the, Prof. F. J. Lewis, 34

Mesothorium 2, α-Rays of, Elisabeth and Rona J. Schintlmeister, 703

Metal-Mining Enterprise, Prof. S. J. Truscott (Warington-Smyth memorial lecture), 964

Metallic: Ions in Alcohol, Study of the Properties of, P. Brun, 300; Phosphides, Preparation by Electrolysis at a High Temperature of, in Particular, of the Manganese Phosphide MnP, M. Dodero, 802; Protection, Selective Oxidation as a Fundamental Principle in, G. J. Thomas and L. E. Price, 830

Metallography: A New Technique, B. Chalmers and W. E. Hoare, 475

Metall-organischen Verbindungen, Die chemie der, Prof. E. Krause und Prof. A. von Grosse (*Review*), 625

Metals: Linear Corrosion of, L. Gindin and F. Semiakin, 91; Spectra of, New Method for Obtaining the, H. Muraour and A. Michel-Lévy, 132; Structure of, Prof. W. L. Bragg and H. Lipson, 367; of the Alkaline Earths, Method of Determining the, G. Wolf, 660; Fusible, Containing Tin, E. J. Daniels, 682; Structure of, R. A. Stephen, 748

Metaphysics, Italian Society of, foundation of an, 73

Meteor: Radiants, Determining, Most Accurate Method for, J. Svoboda, 168; Showers in Japan, Observations of, 881

Meteors: at Great Heights, J. G. Porter, 126; Bright, Shower of, 1094

Meteorological: Office, Annual Report for year ending March 31, 1937, 30; Depressions, A. H. R. Goldie, 209; Organisation for Airmen, 1937, 239; Office of the Air Ministry, impending retirement of Sir George Simpson; appointment of N. K. Johnson as director, 360; Observation in Certain British Colonies; 681

Meteorology in America, [1838], 299

Methallyl Chloride, Control of Insects by, C. J. Briejèr, 1099

Methane Molecule, Structure of the, Dr. H. A. Jahn and Dr. W. H. J. Childs, 916

Methylcholanthrene and Colchicine Administered with Plant Extracts on the Rat, Effects of, Dr. L. Havas and E. Gal, 284

Methylene: Iodide, Photochemical Oxidation of, The Production of Iodic Anhydride, G. Emschwiller, 844; T. G. Pearson, R. H. Purcell and G. S. Saigh, 1106

Meyerstein Institute of Radio-Therapy, Opening of the, 1090

Mice: Male and Female, Adrenal Cortex Differences in, Dr. Ruth Deanesly, 79; Dr. W. Cramer; Dr. Ruth Deanesly, 286; Genotypic Selection for Weight in, Dr. H. D. Goodale, 1104

Microlithic Industries of India, Col. D. H. Gordon, 519

Microliths from the Central Provinces, India, Dr. G. R. Hunter, 208

Microphones, Free Field Calibration of, A. J. King and C. R. Maguire, 1016

Midlands, East, Mineral Resources of the, Dr. D. A. Wray, 106

Milk: Distribution, Retail, Economics of, 41; Supply in Great Britain, Problem of the, Lt.-Col. C. Waley Cohen, 441; Pasteurization of, Prof. G. S. Wilson, 579; -Wool, Dissolving Action of Micro-Organisms on, Prof. J. Smit and B. van der Heide, 647; Industry, River Polution and Waste Waters from the, Dr. A. Parker, 1039; -Wool, Dissolving Action of Micro-Organisms on, W. H. Glover, 1057

Millipedes, Cell Size in, H. G. Callan, 247

Milne-Edwards on Annelidæ, [1838], 299

Mineral: Resources of the East Midlands, Dr. D. A. Wray, 106; Deficiency Affecting Farm Animals, Muriel E. Whalley, 611

Mineralogy: Optical, Elements of, An Introduction to Microscopic Petrography. Fifth edition. Part 1 (*Review*), 952; Petrology and (*Review*), 952

Minerals, Introduction to the Study of, Prof. A. F. Rogers; with a Section on Microchemical Analysis, by Dr. L. W. Staples. Third edition (*Review*), 952

Mines, Chief Inspector of, F. H. Wynne appointed, 550

Mining: and Metallurgy, Institution of, award of the gold medal to Prof. S. J. Truscott and of the Consolidated Gold Fields of South Africa, Ltd. gold medal to Prof. H. V. A. Briscoe, 783; Engineering as a Profession, Dr. C. B. Kingston, 964
MoO_3–NaOH in Dilute Solution, Ultra-Violet Absorption Spectra of the System, Mme. Zina Soubarew-Chatelain and A. Berton, 802
Modern Quarterly, No. 1, 281
Molecular: and Atomic Weights, Determination of, 152; Migration under the Influence of Centrifugal, Osmotic and Electric Forces, Prof. The Svedberg; Dr. A. S. McFarlane, 1000
Molecules: Organic, Primary Photodissociation Processes of, Mechanism of the, Dr. E. Bergmann and Prof. R. Samuel, 832; Prof. R. G. W. Norrish, 1138; Disorderly, and Refrigerating Engineering (James Forrest lecture), Sir Frank Smith, 864; 897
Moll (Prof.), [1838], 131
Mollusca, West North American, A. Myra Keen, 693
Molong-Manildra District Geological Structure and Stratigraphy of the, G. A. Joplin and A. G. Culey, 761
Molybdenum in Nutrition of Milking Cattle, Action of, W. S. Ferguson, Dr. A. H. Lewis and Dr. S. J. Watson, 553
Molybdic Acid, H_4MoO_5, V. Auger, 944
Monaural Threshold: Effect of a Subliminal Contralateral Stimulus, J. W. Hughes, 216
Money, Working of, An Outline of the, Prof. M. Polanyi, 933
Monochromator, A New, Prof. Y. Öhman, 157; 291
Monocotylous Seedlings of Some Dicotyledons, Sir Arthur Hill, 478
Monolayers, Viscosity of, The Surface Slit-Viscosimeter and the Viscosity of, Prof. W. D. Harkins and Prof. J. D. Kirkwood, 38
Monomolecular Films, Viscosity of, D. G. Dervichian and M. Joly, 975
Monotremata, Hairs of the, with Special Reference to their Cuticular Scale Pattern, A. B. Wildman and J. Manby, 343
Montgolfier Balloon, A Large, [1838], 885
Montserrat, Volcanic History of, A. G. MacGregor, 1105
Morpholine, Dipole Moment and Structure of, Prof. J. R. Partington and D. I. Coomber, 918
Morse Telegraph, [1838], 173
Mosaic Crystal Imperfection Effect, Elimination of the, on the Width of X-Lines, J. M. Bačkovský, 872
Motion and Time Study, Prof. R. M. Barnes (*Review*), 460
Motor: Traffic and Wild Life, Surg.-Rear-Adml. Beadnell, 30; Spirit: Synthetic, Production, H. G. Shatwell, 420; from Coal, J. L. Strevens and A. C. Cross, 812; J. E. James; J. L. Strevens and A. C. Cross, 1058
Moulds and the Chemical Industry, R. P. Cook, 209
Mount: Carmel: The Stone Age of, Excavations at the Wady el-Mughara, Miss D. A. E. Garrod and Miss D. M. A. Bate. Vol. 1 (*Review*), 304; Pelé Eruption of May 8, 1902, Relics of the, Dr. C. T. Trechmann, 435
Mountain: Springs, Temperature of, Influence of Melted Snow on the, F. Kerner-Marilaun, 1113; Strata, Distortion of, Isostasy, and Glacial Periods, Sir Joseph Larmor, 906
Mouse: House, Occurrence of a Dominant Spotting Mutation in the, C. C. Little and A. M. Cloudman, 50; Tumours, Effect of Heptylaldehyde on Spontaneous, L. C. Strong, 418
Mucorales in the Soil, Marie E. Campbell, 985
Mummification Technique in Ancient Egypt, 1049
Muscle Tissue, Molecular 'Rejuvenation' of, Prof. G. Hevesy and O. Rebbe, 1097
Museums: Ethnographical, and Empire, 177; and the Research Worker, 193; Display and Reference Exhibits in, S. G. Gordon, 213
Mustelus, Pectoral Bands of, Antagonism in Neurohumours as Seen in the, G. H. Parker, 385
Mutationsforschung in der Vererbungslehre, Experimentelle, N. W. Timoféeff-Ressovsky (*Review*), 139
Mutations, The Experimental Production of, Prof. R. R. Gates (*Review*), 139
"Mysore Tribes and Castes", Appendix to the Four Volumes of the, (Index and Bibliography), late Dr. L. K. Ananthakrishna Iyer (*Review*), 310

NO_3 in the Cubic Crystal, $Ni(NO_3)_2 \cdot 6NH_3$, Evidence of Abnormal Behaviour of, S. H. Yü, 158
N_2H + Ion in the Discharge Reaction between N_2 and H_2, Direct Evidence for the, G. C. Eltenton, 975
Nagpur University, Dr. R. S. Thakur appointed organizing officer in, 240
Narcissus, Leaf Diseases of, Dr. P. H. Gregory, 294
Narcotic Drugs, Toxicology of the, G. R. Lynch, 506
Natal Coal Measures (Middle Ecca Series), Probable Fossil Hail Impressions in, L. E. Kent, 835
National: Institute for Research in Dairying, Anniversary Review of the, 73; Fitness Campaign, The King on the, 362; Survival, Problems of (*Review*), 892; Fitness Council for England and Wales, A Medical Committee Set Up, 969; Physical Laboratory: Prof. R. H. Fowler appointed director of the, 1002; Abstracts, 1007; Report for 1937, 1022; Institute of Industrial Psychology, 1046; Baby Week Council and Physical Fitness, 1051; Institute of Agricultural Botany, M. A. Bailey appointed director of the, 1136
Native Policy in the Union of South Africa, L. Curtis, 404
Natural Resources, Conservation of, 408
NATURE in Germany, Prohibition of, 151
Naturwissenschaftliche Erkenntniss und ihre Methoden Prof. M. Hartmann und Prof. W. Gerlach (*Review*), 954
Navaho: Origin Legend of the, Enemy Way, Father B. Haile, 880
Naval: Architects, Institution of, awards made to R. W. L. Gawn, H. Lackenby and D. N. Wallace, 31; and Marine Engineering, A Short History of, Eng.-Capt. E. C. Smith (*Review*), 1123
Nayadis of Malabar, A. Aiyappan, 611
Nebulæ, Remote, Studies of the, E. Holmberg, 43
Negative Ions at Surfaces, Formation of, Dr. R. H. Sloane and R. Press, 872; Dr. F. L. Arnot and C. Beckett, 1011
Nematode Larvæ, New Method for the Storage of, E. L. Taylor, 205
Nematodes and Insects, Association between, P. Bovien, 758
Nemertean, A Land, in Britain, A. R. Waterston and H. E. Quick, 42
Neodymium and Samarium Acetylacetonates, Influence of the Solvent on the Infra-red Absorption Spectra of Various Solutions of, Mlle. Milka Radoitchitch, 619
Neon and Argon in the Earth's Crust, Lord Rayleigh, 410.
Neurophysiology, Journal of, No. 1, 599
Neutrino, Electromagnetic and, Fields, Connexion between, A. Sokolow; M. H. L. Pryce, 976
Neutro-Electric Effect: Wilson Chamber Photograph of the, S. Kikuchi and H. Aoki, 328; Wilson Chamber Study of the, S. Kikuchi and H. Aoki, 645
Neutron: Proton and the, Magnetic Moments of the, Dr. H. Frohlich and Dr. W. Heitler, 37; -Electron Interaction Proposed by Kikuchi, G. T. Seaborg and D. C. Grahame, 1053
Neutrons, Group *A*, in Silver, Absorption of, Dr. H. Paxton, 971
Newcastle and Carlisle Railway, [1838], 1111
Newton: Kepler and Bode, Prof. G. W. Todd, 412; Isaac, 1642–1727, late J. W. N. Sullivan. With a memoir of the author by Dr. C. Singer (*Review*), 1032
Newton's "Principia", Publication of, [1838], 885
New: Commonwealth Society, Annual Report, 1050; Year Honours, 67; Zealand: Department of Scientific and Industrial Research, Eleventh Annual Report, 638; Earthquake of 1934, R. C. Hayes, 838
Ngoni, War and Morality among the, Miss Margaret Read, 376
Niagara Falls Bridge, Collapse of, 237
Nickel, Bromine, Chromium and Titanium, Packing Fractions of, Dr. F. W. Aston, 1096

Nicotinic Acid in Foodstuffs, A Colorimetric Method for the Estimation of, M. Swaminathan, 830
Night Sky: in January, 114; in February, 240; in March, 365; in April, 549; in May, 782; in June, 968; in July, 1135; Yellow Radiation of the, J. Cabannes and J. Dufay, 567
Nitric Oxide: Disengagement of, by Various Nitrated Products at a Low Temperature, M. Lambrey, 90; NO, Liquid, Magnetic Susceptibility of, H. Bizette and B. Tsai, 1154
Nitrogen: High-Pressure Afterglow in, Prof. J. Kaplan, 645; and Argon in the Earth's Crust, Lord Rayleigh, 970; Influence of, on Growth of Plants, [1838], 984; Line; A New, Prof. J. Kaplan, 1139; (^2P) in the High Atmosphere, Possible Presence of Metastable Atoms of, R. Bernard, 1140
Noise: on the Road, 698; and Housing, 758
Noluas of Bengal, Blood Groups of the, Dr. M. N. Basu, 649
Non-Galactic Nebulæ, Inclinations to Line of Sight of, F. G. Brown, 796
Nordatlantischen Wale und Robben, Naturgeschichte der, Prof. E. Hentschel (*Review*), 494
North: -East Land, Climate of, R. A. Hamilton, 520; Polar Station, Drifting, Scientific Work of the, P. Shirshov and E. Fedorov, 629; America, Exploration of the Coast of, [1838], 701; American Tribes: Social Anthropology of, Essays in Social Organization, Laws and Religion. Presented to Prof. A. R. Radcliffe-Brown upon his accepting the chair of social anthropology at Oxford University, F. Eggan and others (*Review*), 711; Atlantic, Oceanography of the, Problems in the, C. O'D. Iselin, 772
Northern Ireland, Proposed Increased Educational Grants of the Government, 969
Norway, Land-locked Fjords in, Dr. K. M. Strom, 1063
Norwegian Arctic Research, 1050
Noses and Genes, Dr. C. B. Davenport, 418
Nova: Herculis 1934, Spectrograms of, 72; Lacertæ (1936), Objective Prism Observations of, D. L. Edwards and D. R. Barber, 210
Nuclear: Field, Nature of the, Dr. N. Kammer, 116; Resonance Level, Doppler Effect of, Dr. H. von Halban, jun. and Dr. H. Paxton, 116; Forces, Heavy Electrons and the β-Decay, Dr. H. J. Bhabha, 117; Transformation by K-Electron Capture, Dr. E. J. Williams and E. Pickup, 199; Physics and Medicine: Modern High-Voltage Equipment in the United States and on the Continent of Europe, L. G. Grimmett, 311; Photo-Effects, Prof. N. Bohr, 326; Physics (*Review*), 391; Forces, Magnitude of, Prof. G. Beck, 832; Photo-Effects, Resonance in, Prof. N. Bohr, 1096
Nucleic Acid-Protein Mixtures, Electrophoretic Behaviour in, E. Stenhagen and Dr. T. Teorell, 415
Nummulitic, The, of the Valley of Chambres (Nappe de Morcles, Samoens Alps, Haute-Savoie), A. Lillie and W. J. Schroeder, 427
Nutrition: Heat Production, and Growth in Man: Some New Views, Dr. E. P. Poulton, 145; 187; of Schoolchildren, Physical Indices and Clinical Assessments of the, R. H. Jones, 842; The Assessment of, 842; Child, 1067
Nutritional Surveys of Inland Australia: Problems of Child Nutrition, Dr. F. W. Clements, 1023

Oats, Spring, New Varieties of, 407
Oceanic Sedimentation, P. H. Kuenen, 652
Oceanography of the North Atlantic, Problems in the, C. O'D. Iselin, 772
Occupational Diseases, Establishment in Paris of an Institute for the Study and Prevention of, 969
Δ 2–6 Octadiene-1-al, Synthesis of, G. Goethals, 49
Œstrogenic: Activity of Certain Synthetic Compounds, Prof. E. C. Dodds, L. Golberg, W. Lawson and Prof. R. Robinson, 247; Hormones in the Urine of a Pregnant Woman, Spectral Detection of the, H. Bierry and B. Gouzon, 944
Œstrone in Human Male Urine, Chemical Identification of, E. Dingemanse, E. Laqueur and O. Mühlbock, 927
Œstrus, Postponement of Appearance of, Following Interruption of Pregnancy in Lactating Mice, K. Takewaki, 301
Oil: in Osage County, Oklahoma, U.S.A., N. W. Bass, W. R. Dillard and J. H. Hengst, 590; from Coal, Prof. C. H. Lander, 632; 1110; Palm, Stem Rot of the, A. Thompson, 755
Olivine-Fourchites from Antarctica, C. N. Fenner, 1147
Ontario Research Foundation, Report for 1936, 638
Ophiothrix fragilis, Young, within the Genital Bursa of the Adult, Occurrence of, Dr. J. E. Smith, 554
Opium, Indian, Codeine in, Dr. H. B. Dunnicliff, 207
Optical: Projection of Surgical Operations, 780; Illusion, An, L. Pendred, 1018
Optics, Technical, Teaching of, 654, 868
Organ Pipes and Edge Tones, Dr. G. Burniston Brown, 11
Organic: Compounds, Dictionary of. Edited by Prof. I. M. Heilbron and H. M. Bunbury. Vol. 3 (*Review*), 309; Molecular World, A New Guide to the, Prof. J. Read (*Review*), 309; Solvents, Industrial, Toxicity of, Compiled by Dr. Ethel Browning (*Review*), 459; Compounds, Molecular Dimensions of, and the Constant of Dialysis of their Solutions, W. Nowatke, 1029
Organisms, Small Living, Density of, A. G. Lowndes, 979
Organo: -Magnesium Compounds, Double Formula of, J. Décombe and C. Duval, 986; -Metallic Compounds (*Review*), 625
Origanene, Structure of, A. Birch (1), 803
Orkney, Brackish-water Lochs of, Edith A. T. Nicol, 985
Ornithological Society, [1838], 215; 801; 1027
Orthopteroid Insects, Genitalia of, R. E. Snodgrass, 252
Osaka University, *Collected Papers* of the Physics Section for 1936, 29
Osiris, Vol. 3, Pt. 1, 408
Osmosis in Physics and Biology, Prof. E. Ernst, 80
Osmotic: Pressure, J. Duclaux, 166; Values of Plant Tissue under Snow, Dr. and Mrs. H. G. Wager, 652
Ostrea: *edulis*, New Pallial Sense Organs in Early Fixed Stages of, H. A. Cole, 161; *virginica*, Sources of Calcium for Shell of, Dr. P. S. Galtsoff, 922
Otomi of Central America, Dr. J. Soustelle, 124
Ounce Molecular Weight of a Gas, Dr. H. D. H. Drane, 791; J. Strachan; H. V. Thompson, 977
Owen, Richard, receives the Wollaston medal, [1838], 299
Ox, Anatomy of the, H. N. C. Ayyangar, 84
Oxford: Farming Conference, 407; Medical School, Further Gift to, by Lord Nuffield, 18; University, S. J. Wright appointed director of the Institute in Agricultural Engineering; Dr. J. R. Raeburn appointed a research officer under the Committee for Rural Economy; A. G. Ogston elected a fellow of Balliol College; Dr. A. G. Gibson elected a professorial fellow of Merton College; Viscount Cecil of Chelwood appointed Romanes lecturer for 1938; number of students, 89; Dr. H. L. A. Tarr appointed for research work at the Sir William Dunn Institute of Pathology, 156; settlement of a claim against, 238; W. H. Cashmore, J. S. Wilson, R. K. Macdowall and W. J. West appointed rural economy research officers; funds for the laboratory of physical chemistry; grant made towards the university expeditions to the Cayman Islands and to Greenland, 299; programme of development, 505; conferment of a doctorate on Dr. J. R. Baker, 525; A. N. Black appointed demonstrator and lecturer in engineering, 885; M. A. Jennings elected Schorstein research fellow in medicine; Prof. A. C. Hardy granted the degree of D.Sc., 943; Prof. J. H. Muirhead appointed Herbert Spencer lecturer for 1939; R. H. S. Thompson elected fellow and praelector in medical science at University College, 1028; Old Ashmolean, Commemorative Window at the, 1090; University, H. B. Butler appointed warden of Nuffield College, 1112; Dr. M. Cattle appointed tutor in natural sciences at St. Hilda's College; S. Wylie elected a lecturer at Christ Church; Prof. J. B. S. Haldane

awarded the Weldon memorial prize; conferment of honorary doctorates on Sir James Irvine, Lord Desborough, Miss Eleanor Rathbone, Prof. G. I. Taylor and Prof. S. A. Cook, 1153
Oxides: of Iron, Reduction of the, by Carbon Monoxide in the Presence of Some Natural Impurities, F. Olmer, 619; Solubility of, in Fused Boric Anhydride at 1200° C., M. Foex, 619
Oxygen, Deuteron-Induced Radioactivity in, T. Yasaki and S. Watanabe, 787
Oxyhydrate, Hydroxide und, Prof. R. Fricke und Prof. G. F. Hüttig (*Review*), 6
Ozone, Atmospheric, Ultra-Violet Absorption Spectrum of, G. Déjardin and A. Arnulf, 91

Pacific Entomological Survey, 196
Painlevé, Paul, Société des Amis de, 549
Palestine: Archæological Museum, 155; Further Exploration of Tell Duweir, 155; Palæolithic Age in, Abbé H. Breuil (*Review*), 304; The Prehistoric People of, Sir Arthur Keith, 340; Estimated Population of, 935
Palmer's Lactoglobulin, An X-Ray Study of, Dr. Dorothy Crowfoot and D. Riley, 521
Pancreas, Microscopic Anatomy of the, Contributions to the, Paul Langerhans (*Review*), 1038
Pangolin, Chinese Medicine and the, 72
*p*H Scale, The, D. A. MacInnes, D. Belcher and T. Shedlovsky, 1106
Panjab, Archæological Exploration in the, 965
Parallaxes, Accuracy of, Prof. W. J. Luyten, 1021
Paramagnetic: Ions from Magnetic Measurements, Coupling between the Orbital and the Spin Angular Momenta of, Prof. K. B. Krishnan and A. Bose, 329; Absorption, Stimulation of, by a Constant Field, F. Brons and Dr. C. J. Gorter, 369
Paramecium bursaria, Sex Reaction Types and their Interrelations in, H. S. Jennings, 1071
Paris: Academy of Sciences, election as *correspondants* of Prof. Niels Bohr and Prof. G. Denigès, 114; prize awards for 1937 of the, 171; Radium Institute, Dr. A. Lacassagne nominated director of the, 366; New professorships in, [1838], 526; Academy of Sciences, Prof. C. Gutton elected a free academician of the, 601; Annuaire of the, 1093
Parrot's Observations at North Cape, [1838], 484
Pars Nervosa of the Pituitary, Secretory Elements of the, M. Griffiths, 286
Parsons, Sir Charles, The Scientific Activities of, Dr. G. Stoney (Parsons memorial lecture), 185
Partridge, Food of the, Dr. W. E. Collinge, 834
Pascal: and Seventeenth-Century Physics (*Review*), 445; The Physical Treatises of, The Equilibrium of Liquids and the Weight of the Mass of the Air, translated by I. H. B. and A. G. H. Spiers, with Introduction and Notes by F. Barry (*Review*), 445
Pasteur Institute of Southern India, Report for 1936, 549
Patagonia, Succession of Fossil Floras in, E. W. Berry, 50
Patent Law, Reform of the, [1838], 342
Patentees, Institute of, award of medals to Dr. S. C. Blacktin, W. H. Siddle, Mrs. F. Peace, J. R. Churchill, W. McClelland and F. W. Mason, 509
Patents, Designs and Trade Marks, Fifty-fifth report on, 1132
Peace: Science for, Prof. J. Perrin, 151; The Way of, Lord Davies, 442
Peach, History of the, E. A. Bunyard, 838
Pears, Non-Setting of, D. N. Srivastava, 979
Peat, Bio-azotized, Effect of, on Plants, Makinov, 125
Pendulum, Rotating, Some Observations on the, B. H. Crawford, 792
Pennatulacea, The, Prof. S. J. Hickson, 251
Pentaerythritol, Amino-Derivatives of, Dr. F. G. Mann and A. Litherland, 789
Pepsin, Mode of Action of, J. Loiseleur, 133
Permanganate Ions in Violet and Reddish Apatites, J. Hoffmann, 1113
Peroxides, Organic, Decomposition of, E. J. Harris and Prof. A. C. Egerton, 472
Personality, Psychology of, Prof. R. Stagner (*Review*), 448
Peru, Ancient Pottery from, H. J. Braunholtz, 1104
Pests of Ornamental Garden Plants, G. Fox Wilson, 825
Petroleum: Technology, Lt.-Col. S. J. M. Auld (*Review*), 573; The Science of. Edited by Dr. A. E. Dunstan, Prof. A. W. Nash, Dr. B. T. Brooks and Sir Henry Tizard. 4 Vols. (*Review*), 573; Technologists, Institution of, award of the Redwood medal of the, to Dr. A. E. Dunstan, 721
Petrology and Mineralogy (*Review*), 952
Pflanze auf die Andere, Der Einfluss einer, Allelopathie, late Prof. H. Molisch (*Review*), 493
Pflanzen, hoheren, Vergleichende Morphologie der, Prof. W. Troll. Band 1, Teil 1, Lief. 2 (*Review*), 1122
Pharmaceutical Society of Great Britain, award of the Hanbury medal to Prof. A. B. Wasicky, 241; Sir Walter Langdon-Brown and Prof. W. J. Dilling nominated members of the council of the, 641
Phase Rule Equation, A Modified, Dr. S. T. Bowden, 331
Phenazine Derivatives, G. R. Clemo and H. McIlwain, 1148
Phenol Isolated from Various Australian Essential Oils, Constitution of a, A. R. Penfold and J. L. Simonsen, 803
Phenology, Annual Report for 1937, 1047
Philip's Biology Wall Charts, Rev. R. A. Ellis and A. E. Ellis. 16 Parts (*Review*), 854
Philosophy: and the Physicists, Prof. L. Susan Stebbing (*Review*), 307; Science, Logic and, Dr. H. Jeffreys, 672; 716; 977
Phosphatase, A Specific, in the Nervous System, J. Reis, 41
Phosphatases, Vitamin C and, K. V. Giri, 119
Phosphoric Acid, Migration of, Following on the Decalcification of the Phosphatic Chalks with *Belemnitella quadrata* in the North of France, L. Cayeux, 1112
Phosphors without Metallic Activator, W. H. Byler, 1147
Phosphorus, Black, R. B. Jacobs, 209
Photographic Image: R. W. Gurney and N. F. Mott, 612; Latent, Spontaneous Change of the, F. Urbach and A. Wolinski, 703
Photomicrography with the Vickers Projection Microscope, 73
Photosynthesis: in Plants, Mechanism of Propagation of Electronic Excitation Energy, and, Dr. J. Weiss, 248; of Coffee Leaves under Natural Conditions, F. J. Nutman, 252
Phyllirhoidæ of the John Murray Expedition, H. G. Stubbings, 794
Physical: Society's Exhibition, 69; Society, award of the Duddell medal to Prof. H. Geiger, 282; 929; Education for College Women, Measurement of Outcomes of, Elizabeth Graybeal, 477; Association of Frankfort, Dr. F. Bergius elected an honorary member of the, 550; Fitness at Universities, 847; Training, National College of, 1051; Society, Cambridge Meeting, 1149
Physics: College, Prof. J. A. Eldridge (*Review*), 136; Elementary, for Medical, First Year University Science Students and General Use in Schools, G. Stead. Fifth edition (*Review*), 136; Practical, for Inter. B.Sc. Students, Dr. H. M. Browning and L. Starbuck (*Review*), 136; Applied, The Presentation of (*Review*), 224; for Technical Students: Mechanics and Heat, Prof. W. B. Anderson. Third edition (*Review*), 224; in Industry, K. T. Compton and others (*Review*), 224; Social Applications of, Prof. O. U. Vonwiller, 600; Glossary of, Compiled and Edited by Prof. Le Roy D. Weld and others (*Review*), 711; The Pragmatic and the Dogmatic Spirit in, Prof. J. Stark, 770; The Evolution of, The Growth of Ideas from the Early Concepts to Relativity and Quanta, Prof. A. Einstein and L. Infeld (*Review*), 891; Institute of, Board of the, election of officers, 969; Progress in, Tributes to Max Planck, 981; Institute of, Annual Report for 1937, 1005; Sir Frank Smith elected an honorary fellow of the, 1007
Physik, Einführung in die, Dr. O. Bluh (*Review*), 310

Physikalisch-Technische Reichsansalt, The, Fifty Years of Progress, 352
Physiological Society, Prof. A. Krogh and Prof. L. Lapicque elected honorary members of the, 509
Physiologie, chemische, Einfuhrung in die, Prof. E. Lehnartz (*Review*), 535
Physiology of the Individual in the Tropics, Bt.-Col. R. N. Chopra, 380
Phytohormones, F. W. Kent and K. V. Thimann (*Review*), 53
Pig-Keeping, Substitutes for Cereals in, A. N. Duckham, 30
Piltdown Bone Implement, The, J. Reid Moir, 926; Sir Arthur Smith Woodward, 1059
Pine Leaves, Relation between Structure of, and their Position on the Tree, Prof. M. Moissejewa, 649
Pipe Thermostat, 796
Pithecanthropus and *Sinanthropus*, Prof. F. Weidenreich, 361, 378
Planck: Prof. Max, Tributes to, Progress in Physics, 981
Planets, Outer, State of the, Dr. H. Jeffreys, 653
Plankton Diatoms of the Southern Seas, N. I. Hendey, 1026
Planning: Geography the Basis of, Prof. P. Abercrombie and others; S. H. Beaver, 170; in a Democratic Government, Place of, Sir Daniel Hall, 363
Plant: Growth Hormones, Physiological Curve of Response to, N. H. Grace, 35; Ecology: Mrs. Hilda Drabble (*Review*), 392; in Education (*Review*), 392; Physiology: for Students (*Review*), 451; General, E. C. Barton-Wright (*Review*), 451; Growth and Movement, Agents Affecting (*Review*), 493; Hormone Committee, Formation of, 509; Virus: Preparation, A, in a Fully Crystalline State, F. C. Bawden and N. W. Pirie, 513; Research, Recent Developments of, Dr. R. N. Salaman and others, 564; The, and its Water Supply, Prof. E. J. Salisbury (Masters lectures), 658; Protection in the Soviet Union, R. C. Rainey, 756; Design in Electrolysis, Principles of, Dr. H. J. T. Ellingham, 937; Action of One, upon Another, Prof. F. E. Weiss, 1020; Virus Diseases, A Text Book of, Dr. Kenneth M. Smith (*Review*), 1078; Viruses and their Hosts (*Review*), 1078
Plantes: Le milieu et la vie en commun des, notions pratiques de phytosociologie, M.-A. Reynaud-Beauverie (*Review*), 7
Plants: Growth-Regulating Substances in, R. Snow (*Review*), 53; Net Assimilation Rate in, Drift of, O. V. S. Heath, 288; Growth-Controlling Substances in, Dr. H. L. Pearse, 561; of the Sand Dune and Why they Grow there, Prof. E. J. Salisbury, 814; The Naming of (*Review*), 993
Plastics: and Insulation, L. Hartshorn, N. J. L. Megson and E. Rushton, 599; and the Glass Industry, 966
Plato's Conception of Philosophy, Dr. H. Gauss (*Review*), 997
Platynereis, Swarming and Lunar Periodicity of a, R. Gopala Aiyer and N. Kesava Panikkar, 560
Pliny Revived, F. S. Marvin (*Review*), 708
Pneumonia, A New Treatment of, 1131
Polar: Liquid-Liquid Interfaces, Adsorption Potentials at, G. Ehrensvard and L. G. Sillén, 788; Exhibition, International, Projected, 1051
Polarity, Electric and Crystalline, [1838], 1111
Polarized Light, Biot on, [1838], 1068
Polish Universities, Segregation in, 69
Political Arithmetic: A Symposium of Population Studies. Edited by Prof. L. Hogben (*Review*), 892
Polychætes from the Indian Ocean, C. C. A. Monro, 84
Polygenic Conglomerates of the Base of the External Pre-Alps (Voirons, Pléïdes, Collines du Faucigny), A. Lombard, 427
Polymerization: and its Applications in the Fields of Rubber, Synthetic Resins, and Petroleum, Prof. R. E. Burk, H. E. Thompson, A. J. Weith and I. Williams (*Review*), 534
Polyploid Plants, Prof. D. Kostoff (18), 1155
Polypore Fungi, Effects of Radiation on, Prof. S. R. Bose, 936
Pomatoceros triqueter (L.), Tube Formation in, J. D. Robertson and Dr. C. F. A. Pantin, 648
Pontifical Academy of Sciences, Inaugural Meeting of the Second Academic Year, 1109
Portuguese Academy of Sciences, Prof. V. Muller-Hess nominated a corresponding member of the, 469
Postal Reform, The Athenæum and, [1838], 759
Potamogeton densus, Polarity of the Buffer Action in the Tissues of an Aquatic Plant, L. Blum, 945
Potato: Dietary, A Clay Adjunct to, Dr. A. Lawson and H. P. Moon, 40; Virus *X*, Mode of Dissemination of, J. B. Loughnane and Dr. P. A. Murphy, 120; Stocks, Seed, Infiltration of Viruses into, in the Field, Phyllis Clinch, J. B. Loughnane and Dr. P. A. Murphy, 760; Viruses *X* and *F*, Dissemination of, by Leaf Contact, J. B. Loughnane and Dr. P. A. Murphy, 760; Plant, Seasonal Development of the, in Relation to Blight Attack and Spraying, Dr. P. A. Murphy, 844; Virus *X*, Crystalline Preparations of, F. C. Bawden and N. W. Pirie, 1105
Potatoes, Seed, Recommendations for, 934
Power Rectifiers, Progress in, Dr. W. G. Thompson, 695
Practice and Principles (*Review*), 56
Pragmatic, The, and the Dogmatic Spirit in Physics, Prof. J. Stark, 770
Prague, Sero Reactions for Cancer, The, F. Bergh, Dr. O. M. Henriques and J. Schousboe, 751
Precision Gauge for Measuring Liquid in Tanks, 796
Pre-Folsom Man in America, 1004
Prehistoric Man, Duration of Life in, Dr. H. V. Vallois, 292
Prehistory in South Africa, 1115
Press, The, and the Public, 678
Pressure Gradient, Variation of the, with Altitude, G. Tiercy, 485
Primes and Factors, Prof. L. M. Milne-Thomson (*Review*), 454
Prism Objective, Separating Power of the, P. Rossier, 426
Probabilités: calcul des, Les lois des grands nombres du, Prof. L. Bachelier (*Review*), 55; Généralités sur les, variables aléatoires, Prof. M. Fréchet (*Review*), 55
Probability Theory, Recent Developments in (*Review*), 55
Professions, Overcrowded, 303
Progress and Conquest, S. Rivers-Smith and W. K. Spencer. Book 1: The Creation and the World around us; Book 2: The Soil and the Plants (*Review*), 351
Protactinium, Electrolysis of Solutions of, Mme. H. Emmanuel-Zavizziano and H. Haïssinsky, 1028
Protectorates, The, and the Union of South Africa, 663
Protein Breakdown in Germinating Sweet Peas, W. E. Isaac, 520
Proteins, Crystal Structure of the, 521
Protobranch Mollusks, Anatomy of Some, Prof. H. Heath, 293
Proton and the Neutron, Magnetic Moments of the, Dr. H. Fröhlich and Dr. W. Heitler, 37
Protons in the Universe, Mean Free Path of, Prof. E. Schrödinger, 410
Protozoa: Ciliophora, Dr. B. L. Bhatia (Fauna of British India, including Ceylon and Burma), (*Review*), 142
Provence, Pre-Roman, 1025
Psocoptera, Permian Homoptera and, Structure of, Dr. F. M. Carpenter, 164
Psycho-Technical Laboratory, A, 933
Psychology: of International Relations, Dr. W. Brown, 152; Quantitative methods in, Dr. C. S. Myers and others, 613; The Definition of, An Introduction to Psychological Systems, Dr. F. S. Keller (*Review*), 997
Pterinopecten papyraceus and "*Strophomena*" *pecten*, Dr. A. Wood, 1100
Public Analysts and other Analytical Chemists, Society of, election of officers, 509
Puccinia graminis, Fusions between Flexuous Hyphæ and Pycnidiospores in, Prof. A. H. R. Buller, 33
Pulmonés stylommatophores, Chromosomes of the, M. Perrot, 427

Pulverized Fuel in Cylindrical Boilers, Use of, T. F. Hurley, 377
Punjab Irrigation Research Institute, Work of the, 423
Purple, Visual: Scotopic Luminosity Curve and the Absorption Spectrum of, E. Ludvigh, 1141; Sedimentation Constant of, S. Hecht and E. C. Pickels, 1155
Pycnogonida of the John Murray Expedition, 1933–34, Dr. W. T. Calman, 1146
Pyridine, Dipole Moment of, B. A. Middleton and Prof. J. R. Partington, 516
Pyrrolidone: A Chemical Group of Particular Significance to Differentiation, Dr. F. S. Hammett, 82

Quadratic Reciprocity, Law of, N. R. C. Dockeray, 130
Quantenchemie, Einfuhrung in die, Prof. H. Hellmann (*Review*), 667
Quantum: Theory, Relativity and, Prof. Max Born, 327; of Action and Atomic Nuclei, Prof. N. Bohr, 981
Quaternary Glaciations in the Lushan Area, Central China, Dr. J. S. Lee, 499

Rabbit Problem: Pamphlet on the, 640; Control in Australia, 682
Rabies Prevention in India, Dr. R. O. A. Smith, 72
Racemic Compound, A New Method of Resolving a, G. M. Henderson and Dr. H. G. Rule, 917
Radiation: Cooling Curves and the Laws of, C. Handford, 368; Emitted: by Solid Dielectrics Electrified by Friction, F. Perrier, 426; by Electrified Insulators, Determination of the Wave-lengths of the, F. Perrier, 886
Radio: Frequencies, Some Experiments at, on Supraconductors, Dr. F. B. Silsbee, Dr. F. G. Brickwedde and R. B. Scott, 75; activity, Artificial, Produced by α-Particles, L. N. Ridenour and W. J. Henderson, 126; Engineering, Prof. F. E. Terman (*Review*), 308; -Phospholipid, Formation of, by Isolated Tissues of the Rat, A. Robinson, I. Perlman, S. Ruben and Prof. I. L. Chaikoff, 119; -Electric Waves, Sudden Disappearance of, R. Jouaust, R. Bureau and L. Eblé, 343; Research in India, 364; Waves: in the Upper Atmosphere, J. P. M. Mellor, 407; Medium, in the Ionosphere, Magnetic Double Refraction of, Prof. E. V. Appleton, Dr. F. T. Farmer and J. A. Ratcliffe, 409; Activity Produced in Scandium by Fast Neutrons, W. E. Burcham, M. Goldhaber and R. D. Hill, 510; -Waves: Deviations of Short, from the London-New York Great Circle Path, C. B. Feldman, 510; Low-Frequency, Effect of Catastrophic Ionospheric Disturbances on, R. Bureau, 646; Atmospherics, Directional Recording of, F. E. Lutkin, 755; -Element $^{32}_{15}$P, Preparation of, in Weighable Quantity by Means of an Electric Field, J. Govaerts, 871; -Elements, Artificial, Photographic Action of, C. Groven, J. Govaerts and Prof. G. Guében, 916; Reception, Electrical Interference with, A. J. Gill and Dr. S. Whitehead, 941; -Silver, *K*-Electron Capture and Isomerism in, M. L. Pool and E. C. Campbell, 1063; -Element $^{32}_{15}$P, Preparation of, by Means of an Electric Field, J. Govaerts, 1103; Transmitter, N. E. Davis and E. Green, 1108
Radium: -Sensitivity of Cells, Effect of the Medium on, Dr. G. Harker, 84; Uranium and, Radioactive Constants of, S. Meyer, 796
Radon, Estimating, by α-particle counting, Theoretical Efficiency of Cylindrical Ionization Chambers when used for, J. H. J. Poole, 132
Radstadter Tauern, Southern, Structure of the, E. Clare, 133
R.A.F. High-speed Flight, Squadron-Leader J. W. Gillan, 321
Rajputana, Physiography of, Dr. A. M. Heron, 381
Raman: Effect and Analysis, J. Goubeau, 337; Spectra of Liquid Mixtures, Automatic Photography of the, A. Andant, 1154
Randomizing Machine, A, M. G. Kendall and B. B. Smith, 881
Rangoon Zoological Gardens, Dr. B. Barnett appointed superintendent of the, 509
Ranikot Sea, Westward Extension of the, Lt.-Col. L. M. Davies, 202
Ras Shamra, Knossos and, Vaulted Tombs of, Sir Arthur Evans, 124
Rattlesnakes, Removal of Poison Glands of, Prof. J. Tait, 1019
Raum oder Zahl ?, C. H. Tietjen (*Review*), 184
Rayleigh Line in Carbon Disulphide, Diffusion of Light in the edges of the, J. Pniewski, 845
Ray Society, election of officers, 641
Reading: Administratively, W. R. Dunlop, 868; Writing and Speech Problems in Children, Prof. S. T. Orton (Thomas W. Salmon Memorial lectures) (*Review*), 997
Reading University, E. Capstick appointed professor of dairying, 1028
Rearmament and Research: Comparative Costs, 440
Red Sea, Decapod and Stomatopod Crustacea from the, Dr. R. Gurney, 611
Red Spider Mite, Control of the, R. A. H. Gray and H. E. Brooks, 519
Reduviidæ (Rhynchota), Function of the 'Fossula spongiosa' or Spongy Furrow in, N. C. E. Miller, 749
Reflections, Simultaneous, and Deflected Action, Madeleine Blanc and J. Weigle, 427
Refractive Powers, S. S. Kurtz and A. L. Ward, 210
Refrigerating Engineering, Disorderly Molecules and, Sir Frank Smith (James Forrest lecture), 864, 897
Regiomontan, Johannes, Der deutsche Kalender des, Nurnberg, um 1474. Faksimiledruck nach dem Exemplar der Preussischen Staatsbibliothek. Mit einer einleitung von Prof. E. Zinner (*Review*), 532
Regiomontanus and his Calendar, Prof. I. Masson (*Review*), 532
Regional Survey Field Service Pocket-Book, 1094
Reinmuth Earth-grazing Planet, 1937 UB, 113
Relativity and Quantum Theory, Prof. Max Born, 327
Reptiles and Fish, Ears of, Potential changes in the, Prof. E. D. Adrian, 553
Research and Reports, Manual on (*Review*), 310
Resonance: and Mesomerism, Prof. C. K. Ingold, 314; in Tubes, Determination of the positions of, by means of a Galvanometric Deviation, C. Salceanu and C. Istraty, 618
Rheumatic Fever as a Protozoal Disease, Dr. G. A. Stephens, 197
Rhodesian Diptera, Biology of, A. Cuthbertson, 84
Rhodium, Radio, Isomeric forms of, Dr. B. Pontecorvo, 785
R.H.S. Lily Year-Book for 1937, 239
Rice: Plant, Dwarf Disease of the, An Insect Vector of the, T. Fukushi, 175; Cytogenetics of, Dr. S. Ramanujam, 754
Right Ascensions, Comparison of, W. M. H. Greaves, 253
River Pollution and Waste Waters from the Milk Industry, Dr. A. Parker, 1039
Road: The End of the (*Review*), 388; Research: Board, Report for year ended 31st March, 1937, 657; Progress in, 657
Rock-burying Organisms and Coral Reefs, G. W. Otter, 125
Rockefeller Foundation: New York, to give financial support to Profs. A. Kluyve and L. S. Ornstein for radiological investigations, 73; Report for 1936, 867; Barriers to International Aims, R. B. Fosdick, 939
Rocket Apparatus, A Life-saving, [1838], 659
Roman: Fortifications in Yorkshire, J. N. L. Myres and Miss Mary Kitson Clarke, 589; Dorchester, 637; Britain, 938
Root: Formation, Adventitious, Stimulation of, by Chemicals, 88; -pressure as a Factor in the Rise of Sap, Dr. P. R. White, 581
Rose, Writings on the, H. R. Darlington, 1062
Rotating Pendulum, Some Observations on the, Dr. R. J. Lythgoe, 474

Rothamsted: Experimental Station: Dr. E. W. Russell appointed Goldsmiths' Company's soil physicist at the, 198; Report for 1936, 212; Earl of Radnor appointed chairman of the Committee of Management of the, 869; Experiments, Incorporated Society for Extending the, acceptance of the chairmanship by the Duke of Devonshire, 1007
Royal: Academy: Landscape at the, L. C. W. Bonacina, 818; Scientific Associations of the, 821; of Belgium, prize awards of the, 641; Agricultural Society: award of the gold medal of the, to Sir Merrik Burrell, 745; Aeronautical Society, A. H. R. Fedden elected president of the, 1007; Army Medical College, Col. W. B. Purdon appointed commandant and director of studies, and Lt.-Col. D. I. Richardson professor of hygiene, 114; Asiatic Society, Prof. R. Dussaud elected an honorary member of the, 114; Astronomical Society: award of the gold medal to Dr. W. H. Wright and bronze 'Jackson-Gwilt' medals and gift to P. M. Ryves and F. J. Hargreaves, 153; [1838], 258; election of officers, 325; [1838], 659; L. d'Azambuja, Prof. A. O. Leuschner and Prof. K. Lundmark elected associates of the, 683; Botanic Garden, Calcutta, the hundred and fiftieth anniversary of the, 744; College of Physicians of London, election as president of Dr. R. Hutchison, 783; College of Surgeons of England: Research of the, 111; award of the Lister medal to Prof. R. Leriche, 963; Danish Academy of Science and Letters, election as members of Prof. E. Lundsgaard, Prof. H. O. E. Ekwall, Prof. D. Arup, Prof. V. M. Goldschmidt, Prof. H. H. Gran, Prof. T. Frings, Prof. A. Gotze, Prof. R. L. E. Littmann, Prof. R. Goldschmidt, Dr. P. Rous and Prof. A. Thienemann, 783; Gardens, The, [1838], 383; Geographical Society: awards made to J. Rymill, E. Shipton, A. R. Hinks, M. Lindsay, T. Hay, B. Washburn and I. Champion, 589; Royal Premium of the, [1838], 885; Institute of British Architects, award of the Royal gold medal of the, to I. Tengbom, 325; Institution: An Historic Mantelpiece at the, T. Martin, 437; [1838], 801; Annual Meeting; election of officers, 823; Prof. W. L. Bragg elected professor of natural philosophy; Sir J. J. Thomson re-elected honorary professor of natural philosophy, and Sir James Jeans professor of astronomy, 935; Meteorological Society: award of the Symons memorial gold medal to Dr. G. M. B. Dobson, 912; election of officers, 198; Phenological Studies, 1047; Microscopical Society, election of officers, 198; Observatory, Greenwich: Annual Visitation, 1065; Scottish Society of Arts, 239; Society: election of new fellows, 545; election of Prof. J. J. Abel and Prof. N. E. Nørlund as foreign members, 963; Society of Antiquaries of London, award of the gold medal of the, to Sir Charles Peers, 721; Society of Arts, award of prizes for navigation, 1052; Society of Edinburgh: award of the Keith prize to Prof. H. S. Ruse, 469; election of new fellows, 469; award of the Neill prize to Prof. W. J. Hamilton, 826; Society of Medicine, award of the gold medal of the, to Prof. W. Trotter, 783; Society of Tropical Medicine, award of the Manson medal to Sir Leonard Rogers, 864; Swedish Academy of Science, Prof. E. S. Goodrich elected a member of the, 408; Society: Mr. Neville Chamberlain elected a fellow of the, 1135; of Arts, award of the Albert medal to Queen Mary, 1095
Rubber: Structure of, H. A. Morss, jun., 561; Natural and Artificial, The Elasticity of Long-chain Molecules, Prof. H. Mark, 670; Elastic Constituent of, Dr. T. C. Roberts (*née* Marwick), 834; from India, Supply of, [1838], 942
Rubidium and Cæsium Hydrides and Deuterides, Dissociation pressure of, A. Borocco, 1028
Rumanian Academy at Bucharest, Prof. F. Paschen elected an honorary member of the, 1052
Ruminant Nutrition, Cobalt and Copper in, H. R. Marston, E. W. Lines, R. G. Thomas and I. W. McDonald, 398
Russian North Polar Expeditions, [1838], 173
Rutherford, Late Lord: in Manchester, Memories of, Prof. H. Geiger, 244; Dominion Tributes to, 841
Rye-grass, Endophytic Fungi of, Miss Kathleen Sampson, 336

SeO_3'', SeO_4'', AsO_3''', AsO_4''', Simultaneous estimation of, J. Milbauer and J. Vodrážka, 619
Sabellid Worms, Functions of the Tube in, Prof. H. Munro Fox, 163
Saccharum, Hybridization in and with the Genus, Rao Bahadur T. S. Venkatraman, 340
St. Andrews University, H. G. Campbell appointed professor of dental surgery, G. A. Cumming lecturer in geology and geography, J. Dewar lecturer in chemistry in the United College, and Dr. D. Stiven lecturer in bacteriology and assistant director of the Bacteriology Laboratory, 426; Dr. W. F. K. Wynne-Jones appointed professor of chemistry; J. N. Davidson lecturer in biochemistry in Dundee University College, 843
St. Lawrence Island, Alaska, Archæology of, H. B. Collins, jun., 87
Salamander, The, [1838], 1153
Salicylaldehyde Reaction of Csonka-Straub, Specificity of the, Dr. T. Thomson, 917
Salmon: of the River Shannon, A. E. J. West, 48; (*Salmo salar* L.), Life-history of the, Prof. J. H. Orton and J. W. Jones, 1017; Return, 'Spawning Urge', 'Homing Instinct', and 'Waiting' in, Dr. A. G. Huntsman, 421
Salters' Institute fellows, presentation of, to Prof. A. Smithells, 864
Salts, Complex, in Aqueous Solution, Viscosities of some, C. E. Fawsitt and R. W. Stanhope, 761
Sand Dunes, Plants of the, and Why they Grow There, Prof. E. J. Salisbury, 279
Sands, Clays and Minerals, April, 1095
Sap: of a Plant, A Simple Method of Showing Tension in the, Prof. H. H. Dixon and L. A. T. Ballard, 132; Rise of, Root-pressure as a Factor in the, Dr. P. R. White, 581
Saturn's Satellites, Bode's Law and, J. Miller, 245
Scandium, Radioactivity produced in, by Fast Neutrons, W. E. Burcham, M. Goldhaber and R. D. Hill, 510
Scent: Hunting by (*Review*), 451; The Mystery of, Major H. B. C. Pollard (*Review*), 451
Schicksalsstunde Europas: Erkenntnisse und Bekenntnisse, Wirklichkeiten und Möglichkeiten, Karl Anton, Prinz Rohan (*Review*), 854
Schlesinger, Kathleen, research fellowship for 1938–39, Dr. K. Stern appointed to the, 869
School Certificate Examination, Sir Philip Hartog, 71
School Child, Health of the, 1135
Schrödinger Equation, Solutions of the, Prof. E. Schrödinger, 981
Schutz's Law and the Clotting of Blood, Dr. T. Astrup, 1057
Science Abstracts, 1937, 682
Science and Society, Oct.–Jan., 196
Science: and Society: The Advancement of, Proposed World Association, 169; Dr. F. R. Moulton, 517; Prof. P. G. H. Boswell, Prof. F. T. Brooks and Prof. Allan Ferguson, 557; 763; News a Century Ago, 47; 89; 131; 173; 215; 258; 299; 342; 383; 425; 484; 525; 617; 659; 701; 759; 801; 843; 885; 942; 984; 1027; 1068; 1111; 1153; and Mankind, Symposium on, 19; and the Unobservable, Prof. H. Dingle, 21; A Philosophy of (*Review*), 95; to Philosophy, Through, Prof. H. Dingle (*Review*), 95; really Means: What, an explanation of the History and Empirical Method of General Science, J. W. Friend and J. Feibleman (*Review*), 99; Social Relations of, 723; Sir William Bragg, Sir F. Gowland Hopkins, H. G. Wells, Prof. J. L. Myres, 725; Prof. H. J. Fleure, Prof. P. S. Florence, 726; Prof. H. A. Marquand, Prof. H. J. Laski, Prof. M. Ginsberg, 727; A. Farquharson, Prof. C. Spearman, Prof. J. C. Flugel, 728; Dr. C. S. Myers, Prof. F. C. Bartlett, Prof. A. V. Hill, 729; Prof.

J. S. B. Stopford, Prof. J. B. S. Haldane, 730; Sir Peter Chalmers Mitchell, Prof. W. E. Le Gros Clark, Prof. J. Graham Kerr, 731; Prof. J. A. Ryle, Prof. F. A. E. Crew, 732; Prof. E. J. Salisbury, Dr. J. S. Huxley, 733; Dr. J. Needham, Sir Daniel Hall, Sir John Russell, 734; Prof. P. G. H. Boswell, Sir Henry Tizard, 735; Prof. J. D. Bernal, Prof. P. M. S. Blacket 736; Prof. F. A. Lindemann, Prof. H. Levy, 737; Prof. A. Ferguson, 738; Sir Richard Paget, Bt., 738; Prof. A. C. G. Egerton, 739; Prof. F. G. Donnan, 740; Prof. J. Read, Prof. J. C. Philip, Dr. C. H. Desch, 741; Prof. F. Soddy, 784; Dr. W. A. Wooster, 879; 1046; Social Values of, R. Brightman (*Review*), 99; and Ethics, Dr. E. G. Conklin, 101; and Social Problems, 109; and Citizenship, Sir Richard Gregory, Bt., 128; Masters' Association: Annual Meeting, 128; Prof. J. Gray elected president, 129; and Society, A World Association of, 150, 169; for Peace, Prof. J. Perrin, 151; Museum, New Sundials at the, 156; and University Teaching, Dr. W. H. George, 197; in Administration, 219; and Learning, Society for the Protection of, acceptance by the Archbishop of York of the presidency of the, 241; in India, Sir John Russell, 295; 338; 379; and Philosophy (*Review*), 307; Shifting Focus of, 387; in Industry, 432; and Social Welfare in the Age of Newton, Prof. G. N. Clark (*Review*), 463; Forthcoming Books of, 466; and the Unobservable, S. Van Mierlo, 555; Prof. E. H. Kennard, 556; Prof. H. Dingle, 557; History of, and the New Humanism, Dr. G. Sarton (*Review*), 677 Significance of the, F. S. Marvin (*Review*), 677; Logic and Philosophy, Dr. H. Jeffreys, 672; 716; 977; The Social Background of the rise of, in the seventeenth century, Prof. P. M. S. Blackett, 679; at Large (*Review*), 766; and the Home, 780; and Industry, Sir Richard Gregory, Bt., 799; in the Chemical Industry, Major F. A. Freeth, 799; Application of, to Agriculture, Sir John Russell, 799; Advancing Front of, G. W. Gray (*Review*), 852; Frontiers of, C. T. Chase (*Review*), 852; Popular, Dr. W. H. George (*Review*), 852; and Industry at the Empire Exhibition, Glasgow, 860; and the Unobservable, Prof. E. H. Kennard; Prof. H. Dingle, 878; (K'o Hsüeh), Vol. 22. Nos. 1 and 2 (*Review*), 954; Subjects at External Arts Examinations, A. Mole, 978; to Fantasy, From (*Review*), 994; for the Citizen: A Self-Educator Based on the Social Background of Scientific Discovery, Prof. L. Hogben (*Review*), 1075; in the Service of Man (*Review*), 1075

Scientific: and Industrial Research, Department of, Report for the year 1936–37, 432; and Technical Books, Recent, January 29, v; February 26, v; March 26, v; April 30, v; May 28, iii; June 25, v; Centenaries in 1938, Engr.-Capt. E. C. Smith, 13; Film Society, Proposed, 1005; Research: Whole-time awards for, list of, 114; in India, 230; for Britain, A Policy for, Prof. J. D. Bernal, 320; Interpretation and Exposition of, 429; in International Affairs, 947; Works, Old, Publication of, 194; Worthies, XLVIII: Sir Frederick Gowland Hopkins, O.M., F.R.S., 989

Scottish: Universities Parliamentary election, 153; National Museum of Antiquities, A. J. H. Edwards appointed director of the, 930; Marine Biological Association, Annual Report for 1936–37, 1006

Sea-Birds, Destruction of, by Oil, Prof. N. K. Adam, 324

Seasons, Nomenclature of the, Dr. C. H. Pollog, 206

Seedlings, Modifications Undergone by, after remaining a Relatively Short Time in solutions of β-indolylacetic acid, T. Solacolu and D. Constantinesco, 91

Seismic Waves in the Core of the Earth, Prof. B. Gutenberg and C. F. Richter, 371

Seismology: Bibliography of, Dr. E. A. Hodgson, 419; Theoretical, Introduction to, J. B. Macelwane and F. W. Sohon. Part 1: Geodynamics, J. B. Macelwane (*Review*), 628

Selenium, Liquid, Dielectric Polarization of, J. Wesolowski, 49

Senftenbergia ophiodermatica Goppert, *Dactylotheca plumosa* and, Structural features of, N. W. Radforth, 760

Sense Organs, Autonomous Rhythmical Activity of, A. Sand, 285

Sewage Discharge and the Mersey Estuary, Co-operation in Technical Research, 1081

Sex: Hormones: Terminology of, Dr. A. S. Parkes, 36, 73; Rapid Test for, W. Fleischmann and Susanne Kann, 133; and Personality: Studies in Masculinity and Femininity, L. M. Terman, Catherine Cox Miles and others (*Review*), 854; and Society, Prof. E. Westermarck (*Review*), 950; in relation to Society, Havelock Ellis (*Review*), 950; Differentiation of, in the Chick Embryo, Biological Differences in the Action of Synthetic Male Hormones on the, B. H. Willier, Mary E. Rawles and F. C. Koch, 1156

Shearwaters, Large Flights of, H. E. Parmenter, 560

Sheep: Selective Thallium Moult in, Prof. N. A. Iljin, 162; Tick, Activity of the, Prof. J. Hendrick, W. Moore and G. D. Morison, 648

Sheep's Brain: The Dissection and Study of the, as an Introduction to the study of the Human Brain, J. Wilkie (*Review*), 896

Sheffield University, R. W. John appointed research assistant in the department of pathology, D. Harrison assistant lecturer in electrical engineering, and D. Havenhand assistant lecturer in metallurgy, 89; Dr. W. H. Pearsall appointed professor of botany, 525; 545; Dr. R. P. Linstead appointed professor of chemistry in, 929, 943; Prof. Irvine Masson appointed vice-chancellor, 1089, 1112; Dr. E. Leighton Yates appointed assistant lecturer in physics, 1112

Shells, Structure of, [1838], 258

Shield of Nobility of the German Reich, award of the, to Prof. A. Koenig, 869

Siberia, Frozen Soil of, [1838], 383

Silent Social Revolution: The, an Account of the Expansion of Public Education in England and Wales, 1895–1935, G. A. N. Lowndes (*Review*), 487

Silicochloroform, Diffraction of the X-Rays for, M. H. Pirenne, 702

Silicon: Poisoning, A Curious Case of supposed, in the Swan, E. Gray, 163; Monosulphide, Band Spectrum of, R. F. Barrow and Dr. W. Jevons, 833; Monoxide, W. Biltz and P. Ehrlich, 881

Silkworm Eggs, Experiments of Ooplasm Transfusion of, with special reference to the Embryo, Y. Umeya, 301

Silurian Inlier of Lisbellaw, Co. Fermanagh, with a note on the Age of the Fintona Beds, J. C. Harper and J. J. Hartley, 944

Silver Isotope, New Radioactive, H. Reddemann and F. Strassmann, 838

Similarity and Dissimilarity, Dr. W. H. George, 1055

Sinanthropus: *Pithecanthropus* and, Prof. F. Weidenreich, 361, 378; *Pekinensis*, Discovery of the Femur and the Humerus of, Prof. F. Weidenreich, 588, 614

Singapore, Crabs from, Chià-Jui-Shen; M. W. F. Tweedie, 251

Sirius and *Great Western*, Arrival of the, [1838], 759

Skin Transplants between Embryos of Different Breeds of Fowl, B. H. Willier, Mary E. Rawles and E. Hadorn, 50

Sky at Twilight, Variations of Intensity of the Sodium *D* line present in the Spectrum of the Light of the, R. Bernard, 1029

Sliding, Nature of, and the Analysis of Friction, Dr. F. P. Bowden and L. Leben, 691

Slieve Gullion Gabbros, Age of the, Doris L. Reynolds, 694

Slumping, Contemporaneous, and other problems at Bray Series, Ordovician and Lower Carboniferous Horizons in County Dublin, A. Lamont, 526

Smallpox among American Tribes, [1838], 759

Smith: Elliot, Memorial, speech by Prof. J. T. Wilson at the unveiling of the, 983; A Biographical Record by his Colleagues. Edited by W. R. Dawson (*Review*), 1117; Life Work of (*Review*), 1117

Smithsonian Archæological Expeditions, New, 1048

Snowdon, National Forest Park near, 197

Snowfall Survey, British, 195

Soaring Flight, Gliding and, Prof. D. Brunt, 712

Social: Problems, Science and, 109; Imports of Invention, 261; Groups, Co-operation of, Prof. F. C. Bartlett, 519; Relations of Science, 723; Sir William Bragg, Sir F. Gowland Hopkins, H. G. Wells, Prof. J. L. Myres, 725; Prof. H. J. Fleure, Prof. P. S. Florence, 726; Prof. H. A. Marquand, Prof. H. J. Laski, Prof. M. Ginsberg, 727; A. Farquharson, Prof. C. Spearman, Prof. J. C. Flugel, 728; Dr. C. S. Myers, Prof. F. C. Bartlett, Prof. A. V. Hill, 729; Prof. J. S. B. Stopford, Prof. J. B. S. Haldane, 730; Sir Peter Chalmers Mitchell, Prof. W. E. Le Gros Clark, Prof. J. Graham Kerr, 731; Prof. J. A. Ryle, Prof. F. A. E. Crew, 732; Prof. E. J. Salisbury, Dr. J. S. Huxley, 733; Dr. J. Needham; Sir Daniel Hall; Sir John Russell, 734; Prof. P. G. H. Boswell; Sir Henry Tizard, 735; Prof. J. D. Bernal, Prof. P. M. S. Blackett, 736; Prof. F. A. Lindemann, Prof. H. Levy, 737; Prof. A. Ferguson, Sir Richard Paget, Bt., 738; Prof. A. C. G. Egerton, 739; Prof. F. G. Donnan, 740; Prof. J. Read, Prof. J. C. Philip, Dr. C. H. Desch, 741; Prof. F. Soddy, 784; Dr. W. A. Wooster, 879; 1046; Studies, Realistic, 135; Sir William Beveridge, 375; Services, Public, Expenditure on, 1132

Société: de Chimie Industrielle de Paris, Prof. P. Kuhn and Prof. E. Spath elected honorary members of the, 198; Zoologique de France, Dr. W. T. Calman elected an honorary member of the, 683

Society: of Arts, [1838], 48; Science and, The Advancement of, Dr. F. R. Moulton, 517; Prof. P. G. H. Boswell, Prof. F. T. Brooks and Prof. Allan Ferguson, 557; Science and, 763

Sodium: and Potassium Hydrides and Deuterides, Comparative study of the Dissociation Pressures of, A. Borocco, 91; Thiosulphate, Comparative Action of Potassium Iodate and of Potassium Periodate on, in weakly Acid Medium, E. Carrière and M. Delpla, 174; in the High Atmosphere, R. Bernard, 788; Prof. J. Cabannes, Prof. J. Dufay and J. Gauzit, 1054; Isocyanate, Structure of, M. Bassière, 1154

Soil: Fungi, Ecology of, Dr. Jagjiwan Singh, 85; Conservation in Tropical Africa, Dr. L. Dudley Stamp, 268; Erosion: the Growth of the Desert in Africa and elsewhere, Sir Daniel Hall, 394; Blood and, 621; Toxicity in the Dorset Heaths, 798

Soils of Southern England, Pedocalic Tendencies in, Dr. Frances F. Kay, 925

Solanums immune from Potato Blight, B. B. Mundkur, B. T. Pal and P. Nath, 419

Solar: Radiation Constant, British Fisheries, Phosphate and the, Dr. W. R. G. Atkins, 77; Corona ?, Does Iron occur in the, Prof. A. Rubinowicz; Prof. F. J. M. Stratton, 81; Eruptions, Recent, Auroras, and Magnetic Storms, A. J. Higgs and R. G. Giovanelli, 746; Corona and the Prominences, Observations of the, made at the Pic du Midi during 1937, B. Lyot, 802

Solid: Phase, Adsorption of the Components of a, at the Surface, S. Dobinski, 49; Friction, Study of, J. Mercier and J. Dubois, 90

Solids, Chemical Reactions involving, Prof. N. F. Mott, Prof. J. C. Slater, and others, 839

Solvents, Dr. T. H. Durrans. Fourth edition (*Review*), 1123

Sound: in Liquids, Velocity of, Measurement of the, by a Resonance Method, C. Sălceanu, 217; -recording for Films: a Review of Modern Methods, W. F. Elliott (*Review*), 226; Film, Properties of Variable-width, as an Optical Diffraction Grating, Dr. J. F. Schouten, 914; Waves, their Shape and Speed, Prof. D. C. Miller (*Review*), 1119

South Africa: Archæology in, Dr. D. Randall-MacIver (*Review*), 222; Union of, The Protectorates and the, 663; African: Institute for Medical Research, Annual Report for 1936, 444; Exhibits, [1838], 1027; Fruit, Storage of, 1062; Prehistory in, 1115; A Stone Age Rock-Shelter in, A. J. H. Goodwin, 1151

Soviet: North Polar Station, 278; Universities, Salaries in, Dr. H. L. Callendar, 290; M. Ruhemann, 792; Polar Station, Drift of the, 321; Arctic Enterprise, 361; Geography: the New Industrial and Economic Distributions of the U.S.S.R., N. Mikhaylov. Translated by Natalie Rothstein. Second edition (*Review*), 453; Polar Enterprise: Some Preliminary Results, 480; Institute of Physical Problems, Dr. P. Kapitza, 507; awards for North Polar Expedition, 636; Union, Plant Protection in the, R. C. Rainey, 756; Polar Station, The, Prof. R. N. Rudmose Brown (*Review*), 995; Fisheries, Science and the, 1047

Soy Bean, Root Nodules of the, Chan Hsien Wu, 167

Spain: Cave Paintings and Military Operations in, 154; Medical Science in, State of, [1838], 215; Eastern, Cave Paintings of, Prof. H. Obermaier, 251

Spanish Bells, [1838], 984

Special: Areas of Great Britain, Conditions in the, Sir George Gillett, 46; Libraries and Information Bureaux, Report of fourteenth annual conference, 682; work of the, 824

Species: Hybrids, Failure of Anaphase Separation in, H. Klingstedt, 606; Formation, Geographical Isolation as a Factor in, Dr. J. S. Huxley and others, 999

Specific Heats of Solid Metals at High Temperatures, Exact Measurement of the, F. M. Jaeger, J. A. Bottema and E. Rosenbohm (29), 703

Spectrohelioscope with a Vibrating Slit Mechanism, F. J. Sellars, 937

Spectroscopy, Mass, Anomalies Occurring in, H. Lichtblau, 1113

Speech and Civilization, Sir Richard Paget, Bt., 882

Spherical Aberration in Telescopes, Compensation of, C. R. Burch, 294

Spitsbergen, Fault Lines off, Dr. O. Holtedahl, 167

Spore Formation by the Sulphate-Reducing Vibrio, R. L. Starkey, 1155

Spot Method for the Macroscopic Analysis of very small quantities of Liquid, Elisabeth M. Przibram, 259

Spotted Lion, The, K. G. Dower (*Review*), 100

Spring Drought in the British Isles, The, E. G. Bilham, 902

Spruce Sawfly, Cytology of, and its Control in Eastern Canada, Dr. Stanley G. Smith, 121

Star: Variable, *BD*–1° 1004, Photometric Study of the, J. Ellsworth, 48; Cluster, Extra-galactic, Dr. H. Shapley, 636; near New, Discovery of a, Dr. O. Struve, 931

Stars: faint, reduction of Occultations for, Dr. M. Davidson, 337; Occultations of, Degree of accuracy in the reduction of, F. Robbins, 479; Double, Orbits of, Dr. R. v. d. Woolley, 980

Stark Effect, Relativistic, of Ionized Helium, Dr. B. Kullenberg, 244

Starlings Colonizing Canada, L. L. Snyder and J. M. Spiers, 1062

State, The, and Wild Life, 805

Statistical: Studies, Progress of, [1838], 484; Method, Recent developments of, Prof. F. C. Spearman and others, 613

Statistics, Theory of: Dr. J. Neyman (*Review*), 140; An Introduction to the, G. Udny Yule and M. G. Kendall. Eleventh edition (*Review*), 140

Steam Navigation, Early Proposals for, [1838], 383

Steels, Heat Resisting, W. H. Hatfield, 881

Stellar: Universe, A Statistical Survey of the (*Review*), 180; Energy: Origin of, Dr. L. Landau, 333; the Problem of, S. Chandrasekhar, G. Gamow and M. A. Tuve, 982; Statistics, Wave Mechanics and, Dr. H. Jehle, 1148

Stellarstatistik, Lehrbuch der, Prof. E. v. d. Pahlen. Unter Mitwirkung von Dr. F. Gondolatsch (*Review*), 180

Sterols and Related Compounds, Prof. E. Friedmann (*Review*), 459

Stevens, Col. John (1749–1838), 425

Stick Insects, Eggs of, Sister Monica (Dr. Monica Taylor), 1059

Stock and Scion, Incompatibility between, Dr. W. T. Chang, 694

Stockholm Caroline Institute, Dr. Nanna Svartz-Malmberg appointed professor of medicine at the, 241

Stomatal Movement and Epidermal Water-content, Prof. D. Thoday, 164; 608; F. J. Nutman, 608
Stone Age: Cultures, Early, of the Great Salt Lake Region, Utah, 44; Rock-Shelter in South Africa, A, A. J. H. Goodwin, 1151
Storage Batteries, Developments in, E. C. McKinnon, 548
Storms, Energy of, Sources of, Dr. C. W. B. Norman, 295
Stratosphere: The Conquest of the, C. G. Philp (*Review*), 226; Flight, Highest, Observations made in the, 270
Street: Traffic Signals, F. G. Tyack, 365; Lighting, Report on, Dr. J. W. T. Walsh, 599
Stresses, Statically Indeterminate, An Elementary Treatise on, Prof. J. I. Parcel and Prof. G. A. Maney. Second edition (*Review*), 997
"*Strophomena*" *pecten*, *Pterinopecten papyraceus* and, Dr. A. Wood, 1100
Structures and Arches, Continuous, The theory of, Prof. C. M. Spofford (*Review*), 711
Student Health: the Report of an Enquiry into University Health Services by the National Union of Students, 847
Subaqueous Transpiration, Prof. H. H. Dixon, 844
Submarine Light Measurements, Dr. H. H. Poole and others, 1152
Succinic Acid, Effect of, on the respiration of Normal Human Muscle and various Myopathies, Dr. F. J. Stare, E. S. Gordon and M. J. Musser, 831
Sugar: Crystals, Triangular, J. Schmutzer, 133; Beet, Heart-rot of, Dr. Winifred E. Brenchley and Dr. D. J. Watson, 167; Cane × Bamboo Hydrids, Chromosome numbers in, E. K. J. Ammal, 925
Sulphur: Content of the Intercellular Phase of the Wool Fibre, Dr. J. B. Speakman and Dr. P. R. McMahon, 118; reducing acids of, Differential Estimation of the, E. Cherbuliez and Anna Herzenstein, 845
Summer Drought in Caves, Effect on Organisms of, R. S. Hawes, 607
Sun: The Apparent Size of the, A. P. Trotter, 123; at the time of Rising and Setting, Apparent Enlargement of the, Capt. C. J. P. Cave, 290
Sunbeams, 'Convergent': J. J. Hopfield, 333; Dr. A. C. Klebs; A. E. Moon; A. P. Trotter, 558; W. M. Witchell, 559; J. E. Jackson, 1102
Sunspot: A Large, 156; The recent, and Magnetic Storms, 192; Group, A Large, 683; Magnetic Storm and Aurora on May 11, 930; Growth of a, 1007
Sunspots and their Effects, H. T. Stetson (*Review*), 456
Superlattices, Factors influencing Stability of, R. Hultgren and L. Tarnopol, 473
Super-Novæ, The New, F. Zwicky, 481
Supraconductors, The Intermediate State of, Dr. L. Landau, 688
Surgery, Clinical Research in, Establishment of a unit for, at Edinburgh with W. C. Wilson as director, 745
Sussex, The Archæology of, Dr. E. C. Curwen (*Review*), 456
Swan, supposed Silicon Poisoning in the, A Curious Case of, E. Gray, 163
Swedenborg, Emmanuel (1688–1772), 192
Sweet Peas, Protein breakdown in Germinating, W. E. Isaac, 520
Swiss Rontgen Society, election as honorary members of, Dr. C. T. Holland and Profs. R. Kienbeck, Holthusen, H. Meyer, Perussia, De Quervain and Regaud, 1136
Sylviculture, Revue de, Prof. H. Perrin, 239
Synaptic Transmission (*Review*), 266
Syria: North, Excavations in, Sir Leonard Woolley, 194; Archæological Expedition to, 279; Northern: Expedition to, 405; Line of Levels Across, [1838], 759; Ancient, Peoples of, Sidney Smith, 1131

Tables Annuelles Internationales de Constantes et Données Numériques: 14: Combustion and Detonation of Gases, Prof. P. Lafitte. Vols. 11 and 12 (years 1931–1936) Section 70 (*Review*), 628; Vol. 11 (years 1931–1934). Part 1 (Sections 1–25) (*Review*), 997
'Take-all' Fungus, Soil Conditions and the, S. D. Garrett, 694
Talbragar Fish-bed Area, Stratigraphy and Physiography of the, J. A. Dulhunty, 803
Tartaric, Citric and, Acids, Solubilities of, L. H. Dalman, 253
Tasmania, Land Utilization Regions of, A. G. Lowndes and W. H. Maze, 867
Tata, Lady, memorial fund, award of grants and scholarships from the, 1136
Teachers in Technical Institutions, Association of, Annual Conference at Leeds, presidential address by A. C. R. Ritchie and address by Prof H. Levy, 1109
Teaching, Obstacles to, Mrs. E. V. Parker, 781
Telegraphy and Telephony: Progress in the General Post Office, Sir George Lee, 658
Telepathy, Scientific Tests of, Surgeon Rear-Admiral C. M. Beadnell, 878
Telephone Circuit Noise Meters, H. R. Harbottle, 681
Telephony: Telegraphy and, Progress in the General Post Office, Sir George Lee, 658
Telescope Drive, A Variable-Frequency, H. W. Cox, 881
Telescopes: Protection for, F. R. Clark; F. O. Smith, 126; Axial Obstructions in, Diffraction effects due to, H. E. Dall, 420
Television: Receivers, D. C. Espley and G. W. Edwards, 113; Colour, at the Dominion Theatre, London, 278; Theory and Practice, J. H. Reyner. Second edition (*Review*), 461; Co-axial Cables for, Development of, 482; Broadcasting, Major Tryon, 506; Service, London, T. C. Macnamara and D. C. Birkinshaw, 781; 1108; Transmitter, Paris, 824
Tell Duweir, Palestine, Further Exploration of, 155
Temperature, Local Variations of, A. B. Tinn, 980
Temperatures and Pressures in a Closed Vessel, Calculation of the, G. Robaud, 174
Terrestrial Life", "Foundations of, Prof. F. Allen, 610
Testing Stations, Short-Circuit, 1093
Tetrapods, Ancestry of the, T. S. Westoll, 127
Tetrastichia bupatides, A Carboniferous Pteridosperm from East Lothian, W. T. Gordon, 760
Thames: Barrage, Proposed, 362; Tunnel, Flooding of the, [1838], 525
Thermal: Conductivity at Low Temperatures, Prof. W. J. de Haas, 1053; Expansion and 'Co-operative Phenomena', Dr. R. Eisenschitz, 1143
Thermionic Valves, Fluctuation Noise in, D. A. Bell, 833
Thermodynamical Principles, Modern, An Introduction to, A. R. Ubbelohde (*Review*), 464
Thermodynamics, Prof. E. Fermi (*Review*), 464
Thioacids, On, Mlle. France Bloch, 802
Thomson: Effect of Supraconductive Lead, Dr. J. G. Daunt and K. Mendelssohn, 116; Bridge, Accuracy of Measurements with the, P. Rossier, 845
Thucholite, Uranium, Thorium and Lead in, O. B. Muench, 168
Thymonucleic Acid: Molecular Shape and Size of, R. Signer, Prof. T. Caspersson and Prof. E. Hammarsten, 122; X-Ray Study of, Dr. W. T. Astbury and Florence O. Bell, 747
Thyreotropic Hormone, Test for, W. Fleischmann and Susanne Kann, 259
Thyrite Surge Diverter, 130
Thyroid Gland, Histamine and the, Dr. F. Ellinger, 1014
Tidal Lands, Reclamation of, O. Borer, 443
Tide Gauge, A New, [1838], 526
Tides of the British Isles, Prof. G. R. Goldsborough, 1066
Tierwelt Deutschlands, Die, und der angrenzenden Meeresteile nach ihren Merkmalen und nach ihrer Lebensweise, Begründet von Prof. F. Dahl. Teil 31 und 32: Spinnentiere oder Arachnoidea. vii: Wassermilben oder Hydracarina (Hydrachnellæ und Halacaridæ). Teil 33: Spinnentiere oder Arachnoidea. viii: Gnaphosidæ, Anyphænidæ, Clubionidæ, Hahniidæ, Argyronetidæ, Theridiidæ (*Review*), 1080
Tin: Pest, Acute, E. Cohen, W. A. T. Cohen-de Meester and J. Landsman, 133; Thin Layers of, and other metals, Research on, P. J. Haringhuizen and D. A. Was (4), 568
Tissu, Histoire générale du, E. Cherblanc. Document No. 2. Partie 1 (*Review*), 1038

Titanium, Bromine, Chromium, Nickel and, Packing Fractions of, Dr. F. W. Aston, 1096
Toads, Sexual Maturity in immature Male and Female, Stimulation of, under the influence of Pre-Pituitary Extracts, R. Duvaz, 945
Tobacco: Seed Globulin, Molecular Weight of a, Dr. Dorothy Crowfoot and Dr. I. Fankuchen, 522; Leaf-curl in Northern India, Dr. B. P. Pal and R. K. Tandon, 880
Torch-Bearers, The, A. Noyes (*Review*), 184
Totemica: a Supplement to "Totemism and Exogamy", Sir James George Frazer (*Review*), 489
Transatlantic Steam Navigation: 505; One Hundred Years of, H. P. Spratt, 540; A Century Ago, 566; J. W. Morgan, 966
Transformer Windings, Effects of Impulse Voltages on, Dr. T. E. Allibone, D. B. Mackenzie and F. R. Perry, 45
Transmutation of Matter, late Lord Rutherford, 58
Trasenster medal and diploma of the Association des Ingénieurs de Liège, award of the, to Sir Robert Hadfield, Bt., 550
Tree Lover, Vol. 2, No. 21, 444
Trees and Shrubs of the British Isles, The Observer's Book of, W. J. Stokoe (*Review*), 351
Tribe, A, in Transition: a Study in Culture Pattern, Dr. D. N. Majumdar (*Review*), 450
Tring Museum, Lord Rothschild's bequest of the, to the British Museum, 722
Triode Valves, Electronic Oscillations of, E. Pierret, 527
Triticum monococcum, Heterochromatin at the Distal Ends of the Chromosomes in, Prof. D. Kostoff, 690
Trochus niloticus, Habitat and Habits of, H. Srinivasa Rao, 560
Tropical Fruits and Vegetables, Transport of, 866
Trout-marking in Massachusetts, R. A. Nesbit and J. A. Kitson, 125
Tuberculosis: Cuban Campaign against, 826; in the Far East, 72
Tudor Times and After, Scientific Thought in (*Review*), 665
Tumour Glycolysis, *d*-Glyceric Aldehyde and, Dr. B. Mendel, Frida Strelitz and Dorothy Mundell, 288
Tungstic Acid and *o*-Oxyquinoline, Formation of the compound of, S. Halberstadt, 91
Turpentine, Wood, American Steam-Distilled, 1148
Tyrocinium Chymicum, Jean Beguin and his, Prof. T. S. Patterson, 19

Ultracentrifuge: Sedimentation Curves, Direct photography of, J. St. L. Philpot, 283; a Simple Inexpensive, Prof. J. W. McBain and F. A. Leyda, 913
Ultra: -sounds in Liquids under Pressure, Propagation of, P. Biquard, 944; -Violet Rays through Chitin, Penetration of, Dr. G. Eloff and V. L. Bosazza, 608; -Sound Waves, Biological Effects of, 1094; -Sounds, Transparency of Solid Plates to, E. Baumgardt, 1154
U.S.A.: Deaths from motor-vehicle accidents in 1937, 366; Basin Cultivation in the, L. Olson, 858; Public Affairs Pamphlets, 867; National Academy of Sciences, award of the Agassiz medal for oceanography to Dr. E. J. Allen, 869; Mortality in the (*Review*), 953; National Academy of Sciences, election of foreign members, 964; Education in 1932–34 in the, 1134
Units, Systems of, Formation of, Prof. W. M. Hall, 1133
Unity School, Fifteenth, 1092
Univers 1937: quelques aspects de l'astronomie contemporaine, Prof. P. Coudero (*Review*), 494
Universe: Expanding?: Is the, Prof. W. M. Smart (*Review*), 446; Problem of the, Dr. H. Shapley, 1071; Surveyed: The, Physics, Chemistry, Astronomy, Geology, Prof. H. Richards (*Review*), 852
Universities: Continental, [1838], 131; Bureau of the British Empire, Report for 1936–37, 406
University: Graduates, Training and Employment of, 51; College of the South-West of England, 'Vocational Guidance' pamphlet, 240
Upper Atmosphere, Sodium in the, J. Cabannes, J. Dufay and J. Gauzit, 943
Uranium: Crystal Structure of, C. W. Jacob and B. E. Warren, 294; and Radium, Radioactive Constants of, S. Meyer, 796
Uranus, Mass of, [1838], 425
Urea: Secretion, A Contradiction in the present Clearance-Reabsorption views of, Prof. E. J. Conway, 471; Possible role of, in formation of Cancerous Growths, J. C. M. Gardner, 692

Vol. 141 SATURDAY, JANUARY 1, 1938 No. 3557

Jubilee Meeting of the Indian Science Congress

THIS week, the twenty-fifth meeting of the Indian Science Congress Association opens in Calcutta, the jubilee being marked by the attendance of a strong delegation from the British Association; Lord Rutherford was to have presided at the meeting, but fate decided otherwise, and the Association has been fortunate enough to persuade Sir James Jeans to take his place. It may be hoped that this meeting will confirm the growing appreciation in India of the value of modern science.

In the address prepared for the meeting by Lord Rutherford before his death, he pointed out that prior to the first decade of this century, scientific research in India was, with a few notable exceptions, confined to the great scientific services, initiated and maintained on a generous scale by the Government, such as the Survey of India, the Geological Survey, the Botanical Survey, the Departments of Agriculture and Meteorology, and others. To the work of members of the Trigonometrical Survey we owe the principle of isostasy, while the development of the mineral resources of the country has been due largely to the activities of the Geological Survey. In forestry, the fine research institute at Dehra Dun is a monument to the enthusiasm of past members of the Indian Forest Service. The Indian Medical Service has been the means of giving the world, not India alone, new weapons for the attack on tropical diseases such as malaria, cholera and leprosy.

While this work was going on steadily, the Indian universities were being founded, and at first attention was mainly directed to the instruction and examination of students. There were always a few, however, who realized the role the universities must eventually take in the promotion of research, and, as a result of the Curzon Commission on Education in 1904, many of the universities introduced honours courses, and by new appointments and improvements in laboratories stimulated research in science. Amongst the pioneer men of science in India who distinguished themselves by original investigations, Lord Rutherford mentioned in his address Sir Alexander Pedler, Sir J. Chandra Bose, Sir Alfred Bourne and Sir Prafulla Rây.

For geographical reasons, personal contact between scientific workers in India is difficult. Occasional meetings of specialists may be arranged by the Board of Scientific Advice, but these meetings do not affect the university teachers, and in the autumn of 1911 two newly appointed professors, P. S. MacMahon in Lucknow and J. L. Simonsen in Madras, feeling the isolation in which they worked, considered that the time was ripe for the organization in India of a body having the same aims and functions as the British Association for the Advancement of Science. After considerable discussion, and acting on the advice of Sir Thomas Holland, a small committee was constituted to consider the formation of such a body. This committee met on November 2, 1912, and it was decided to ask the Asiatic Society of Bengal (now the Royal Asiatic Society of Bengal), to arrange for the holding of a Science Congress in Calcutta in January 1913. Various difficulties, however, necessitated the postponement of this meeting until January 1914. The arrangements for the meeting were in the hands of the Royal Asiatic Society of Bengal, and thus commenced an association to which the Congress undoubtedly owes much of its success. The organization of the Congress has followed closely that of the British Association although, in view of their special importance in India, sections of medicine and veterinary science were included.

The numbers attending the first meeting, when the late Sir Asutosh Mukherjee, vice-chancellor of the University of Calcutta, was president, were small; some thirty scientific communications were read, mainly by authors resident in Calcutta or its vicinity. This appeared to justify the critics of the scheme who had suggested that geographical difficulties would preclude its success. However, the Government of India early recognized the potential value of the Congress and authorized the payment of expenses to selected Government servants. As a result, the second meeting, in Madras in 1915, was more largely attended and communications were received from authors as far distant as the Punjab and Ceylon. Since these early days, the Congress has grown very greatly, as shown by the size of the *Proceedings*, which in 1914 filled six pages and in 1928 four hundred and twenty.

Whilst this increase in the number of communications read to the various sections provides evidence of the growth of scientific inquiry in India, the main success of the Congress has been, as the original promoters had hoped, in the social contacts which it has provided and the public interest in science which it has aroused in the various centres it has visited. It has stimulated also the formation of such specialist societies as the Indian Botanical Society and the Indian Chemical Society.

While substantial progress in both teaching and research has been made by the universities of India, their responsibilities—and with them those of the Indian Science Congress Association—must inevitably increase. In this present scientific age, efforts are everywhere being made to develop natural resources to the utmost, to improve industrial processes and to increase our knowledge in pure science. It is to the universities and technical institutions that we must look for men to carry out this work. The universities must be able, not only to give instruction, but also to select those who are to be trained in the methods of research. From the latter we may expect to obtain future leaders of research, on whom the prosperity of the country will largely depend.

The utilization of science implies, moreover, a planned scheme of research. Here the experience of some of the Overseas Dominions may prove of service to India. In Canada and in Australia, there are State or Provincial Governments as well as a Federal Government, and in both cases it has been found expedient that the research organization of the country should be truly national and responsible to the Federal Government alone. Even in an Empire the size of India, where the resources and needs of various provinces are widely different, it would seem that centralized organization of research is the only way of avoiding waste of money and effort. The detailed planning of research must be in the hands of those with the necessary specialized knowledge, and they must be able to act without suspicion of political or racial influence. Here the Indian Science Congress Association has shown, over a long period of political turbulence, what can be accomplished, for a marked feature of the Congress has been the complete absence of racial and communal strife; it has remained quite unaffected by these tragic influences, doubtless due in part to the tact of the various general officers and to the very valuable services of the secretary of the Royal Asiatic Society of Bengal, Mr. J. van Manen.

Since the foundation of the Indian Science Congress Association, it had always been hoped that it might prove possible to arrange for an over-seas visit of the British Association to India. The necessity, for climatic reasons, of holding such a meeting during the cold weather (November to February), the middle of the academic year, offered serious difficulties. However, they have now been overcome, and, moreover, the precedent has been established of sending a delegation to a joint meeting with another organization. This is undoubtedly of great significance. Valuable as are personal contacts within a country, such contacts with workers in other countries and the opportunity of seeing the conditions under which they work are of even greater value, while the presence of a body of distinguished scientific visitors in India cannot fail to be a source of inspiration to students and scientific investigators in that country.

Medicine as a State Service

Socialised Medicine in the Soviet Union
By Dr. Henry E. Sigerist. Pp. 382. (London: Victor Gollancz, Ltd., 1937.) 15*s.* net.

DR. HENRY SIGERIST was the successor of his great master Sudhoff as professor of the history of medicine at Leipzig, and now occupies a similar post at Johns Hopkins University, Baltimore. He is a prolific writer of popular books on historical subjects related to medicine, and many readers of NATURE will know his books on "Man and Medicine" and his biographical account of "Great Doctors". He has now embarked upon a survey of the medical policy of the Soviet Union, of which he appears to be a warm admirer. Indeed, it is not too much to say that he is something more than favourably disposed, and this should be borne in mind in weighing his evidence. Sidney Webb, well known as an advocate of Soviet policy, furnishes a foreword to the book, and concurs in Prof. Sigerist's view that the Soviet method is planned throughout on a scientific basis. It banks on science for its salvation. As Sidney Webb says elsewhere (1937),

> "it refuses to accept as knowledge or as the basis of its code of conduct any of the merely traditional beliefs and postulates about man and the universe for which no rational foundation can be found, or any of the purely subjective imaginings of the meta-physician or the theologian".

Prof. Sigerist vigorously criticizes what he calls the 'compromise system' of the capitalist countries in respect of medicine. State medicine, he says, insurance medicine, charity medicine and private medicine exist side by side. The fight against disease is not planned, not led by one general staff; it is without design, and with all the deficiencies of a compromise. In other words, it has grown, in response to need, over the centuries, charity medicine (or medical alms-giving), organized private practice, a public health service, health insurance—which is the more correct order of events—emerging as "individualism" and becoming more fully organized as the community requires. Dr. Sigerist finds this historical process unsatisfactory, and prefers the Soviet model. The Soviet health system is described in these words:

> "(1) Medical service is free, and therefore available to all, (2) the prevention of disease is in the foreground of all health activities, (3) all health activities are directed by central bodies, the People's Commissariats of Health, with the result that (4) health can be planned on a large scale."

This definition is clear, and not unappetizing, but to the ancient world (which, *inter alia*, is England) it has, at first sight, the appearance of one more top layer super-added to the palimpsest. In the author's view, shared presumably by everybody, this plan can only be that of a Marxist socialist State. He claims if a society is to function successfully it requires healthy members; to obtain them health must be accessible to all, and free of charge. Medicine, like education, must be, he says, not a trade but a public function of the State.

> "The great majority of the population (74 per cent in 1934, more to-day) consists of wage-earners and collective farmers. The wage-earners receive their wages from the State as all enterprises are State enterprises. The collective farmers sell their crops to the State. Both groups purchase whatever they buy from the State. All money goes therefore from the State to the population and back to the State, which redistributes it every year. In the course of production, surplus values are created which are controlled and distributed by society through its various agencies. Part of this surplus serves to finance the health work of the nation."

The scheme begins with the most complete social insurance system, the costs of which are part of the cost of production; the health work is operated and controlled by the Commissariats of Health and their subordinate organs, at the cost of insurance surplus and the local central budgets; the system is designed to be preventive, and "prophylaxis is in the foreground of all medical considerations"; the Soviet medical man is not a private practitioner but a civil servant, a citizen and a worker, and all his actions are for the benefit of society; a Scientific Medical Council advises the Commissariat in all medical matters, distributes the doctors and differentiates their work, and organizes research.

> "The State has but one purpose, to promote the welfare of the people, of all the people, without distinction; to raise the material and cultural standard of the population; to liberate man from the bonds of poverty, of ignorance and disease. This and only this justifies the existence of the State."

In the Soviet Union, where physicians work on a salary basis, fees and the money issue are eliminated. Medical service is given through health centres of various kinds, dispensaries, polyclinics, ambulatoria, preventoria, prophylactoria, or hospitals. Certain groups are especially provided for, such as labour or mothers and children, and these are often dealt with at the factory clinic or at the school. For bed cases institutional treatment is available. Physical culture and recreational exercise are encouraged and provided for. Convalescent homes and popular resorts are developed, as also are housing reform and food supply, all on a more or less communal basis. Social diseases (tuberculosis, venereal, prostitution, abortion) are especially dealt with, and as they are common a large and elaborate organization has been set up. In 1920, as is well known, the Soviet Government legalized abortion and the practice spread rapidly, but in 1936 a law was passed making abortion a criminal offence, and providing new facilities for maternity, infants' nurseries and family allowances.

Neither Dr. Sigerist nor anyone else can say how this vast experiment will turn out. Indubitably it is favoured by the mass of the population, and in the cities is bringing a measure of health never known before in Russia. Apart from the wild scheme of encouraging abortion, maternity and childhood are safeguarded, insurance is more complete than elsewhere, and abundant amenities are brought to a people accustomed to few or none. It is too early to consider vital statistics. The imposition of so huge a medical scheme, varied and costly, inelastic and continually being altered, at such incredible speed, would seem to be courting disaster, yet it is being accepted by a communistic world. As for the future, Dr. Sigerist is sanguine and confident. He has certainly produced the most interesting book which has yet been written on the organization of medical science in Russia. This is not the occasion to explain the cogent reasons why the Soviet system of State Medicine cannot be adopted in Britain, though we should be wise to learn from it what we can.

GEORGE NEWMAN.

Chemistry of the Cell Wall

The Biochemistry of Cellulose, the Polyuronides, Lignin, etc.
By Dr. A. G. Norman. Pp. ix + 232. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 15*s*. net.

DR. A. G. NORMAN has done a real service to an increasing number of research workers by putting together the literature relating to the very complex group of compounds which constitute the cell wall of plants. The field is a developing one of scientific interest and technical importance, the established facts are few and somewhat scattered, whilst the literature retains much that is unsound. He is not afraid to give a lead at times in being both critical and trying to give the right perspective: in our opinion the book forms a platform from which future work can be initiated on sounder lines than in the past, and as such should be widely and carefully read.

Cellulose has been closely studied by chemists, who have cleared up most of its structural problems: there is a controversy as to whether its chain of glucose molecules joined end to end is a mere one to two hundred units long, as postulated by the Birmingham School, or whether it is ten times greater in length as is even more widely held and is indicated by physical measurements. Prof. W. N. Haworth gets out of the difficulty by joining his molecules together by co-ordination valencies, whereas the opponents do not see any reason to discard chemical valencies: it is considered that Haworth worked with an already degraded cellulose.

It is a moot question whether any of these large molecules can be properly considered as defined chemical entities. In the cell, where they have visible structure, the aggregate number of unit molecules is a very large one; probably the attempts to transfer the substance from the cell to the laboratory flask result in its simplification. Indeed, if the process be carried too far, there is a definite change in physical property, as, for example, loss of tensile strength in a degraded cotton, which has been proved to have a shorter average chain-length.

Cell wall chemistry would be relatively simple if glucose were the only sugar elaborated by the plant. In fact, it produces also galactose and mannose, which are isomeric with glucose, also two pentose sugars, xylose and arabinose, and possibly still other of the many isomeric sugars that are theoretically possible but which are difficult to identify. In addition, there are the uronic acids, which apparently make up the whole molecule of pectin and can be regarded as the half-way stage between the hexose and pentose sugars: it is considered that xylose is made from glucose in the plant and is not a product of original synthesis. The process involving oxidation followed by decarboxylation has so far baffled observation, and therefore particular interest attaches to recent work of Campbell in which he has obtained carbohydrates from wood and from oak leaves, representing as it were a transition stage between starch and the mixed polysaccharides.

In studying such substances the initial difficulty is to obtain them sufficiently free from similar compounds to make them worth analysis and at the same time not to break them down during the process of purification. Where this has been accomplished, results have begun to accrue which are startling in the sense that they disclose a greater complexity of structure than might perhaps have been expected. Whereas in cellulose, as also in starch, the end carbon of one little six carbon chain-molecule of glucose is joined to the fourth carbon from the end of the next glucose, it is found with the so-called hemi-celluloses that the join is to the sixth carbon and sometimes to the fifth carbon.

Whilst the natural syntheses are definitely selective and no doubt catalysed by an enzyme, it is clear that many alternative syntheses which the chemist can picture on paper also take place under other conditions and give rise to substances which though closely similar are intended to meet other functional ends.

Incidentally, the term hemi-cellulose is unfortunate, as these compounds are in no sense degradation products of cellulose or even related to it: the author suggests the term amylo-uronides in substitution.

It is possible only to indicate a few of the problems covered by the book: it also includes a chapter dealing with lignin, a polymeric material containing an aromatic group on which much work is still to be done. E. F. A.

Babylonian Mathematics

Mathematische Keilschrift-Texte

Herausgegeben und bearbeitet von O. Neugebauer. Teil 3: Ergänzungsheft. (Quellen und Studien zur Geschichte der Mathematik, Astronomie und Physik, herausgegeben von O. Neugebauer und O. Toeplitz, Abteilung A: Quellen, Band 3.) Pp. vi + 83 + 6 plates. (Berlin: Julius Springer, 1937.) 26.60 gold marks.

THIS Part 3 of the volume of mathematical cuneiform texts forming vol. 3 of Section A of the "Quellen und Studien zur Geschichte der Mathematik, Astronomie und Physik", though only supplementary to Parts 1 and 2, published in 1935, is a substantial volume of more than 90 large quarto pages, and contains additions and corrections necessary to make the volume complete. It includes texts which have become known to the editor since 1935 and revisions of a number of the texts which were included in the earlier parts, but could not then, owing to illegibility or otherwise, be dealt with more than provisionally.

In the meantime, other workers in the same field have been active; the first text, that of British Museum No. 13901, was first published by Thureau-Dangin in 1936; the second (B.M. 34568) was almost entirely contributed by Waschow; the third in Chapter i, one of the texts of the Yale Babylonian Collection (Y.B.C. 6504), was first recognized as mathematical by A. Götze, and F. J. Stephens helped in preparing the text. Chapter ii contains improved texts of the inscriptions belonging to the Yale collection mostly included or mentioned in Part 2; chapter iv (15 pages) is important, giving many additions and corrections to Parts 1 and 2. There are substantial improvements, again owing much to the labours of Thureau-Dangin, Waschow, O. Becker, Kurt Vogel, Bartolotti and others. Chapter v gives a complete glossary to the texts dealt with in chapters i to iii and additions and corrections to the glossary in Part 2; in chapter vi we have observations on the general character of the Babylonian achievements in mathematics, with fresh indications of their nature furnished by astronomical texts. Special attention should be directed to chapter vii, containing indexes, the last of which is a "Sachregister", or index to the subject-matter, of all three parts. Such an index is absolutely indispensable in a work of this kind; and the present one does not fail us.

The editor seeks to show that, not only in astronomy, but also in the purely mathematical domain, there existed, in addition to the texts which we have, and which contain multitudes of examples worked out on uniform lines but without any statement of general rules, works containing such rules and deserving to be described as 'text-books'. This view is, he thinks, supported by one or two passages where we are told what to do in general terms, as in the following case from B.M. 34568: "Take (*a*) the sum of the length, breadth and diagonal and (*b*) twice the area. Subtract the latter from the square of the former. Take the half of the remainder", and so on. These cases may indicate that there existed formulæ for solution stated generally and not merely in the concrete numbers of a particular case; but it still seems that we look in vain for any indication how the formula was arrived at, and for anything of the nature of a *proof* of its correctness.

Among details calling for notice are the following: (1) The consideration of the text of B.M. 13901, which goes back to the Hammurapi period, shows that it deals with the same type of problem as what the editor calls "Serientexte", which must therefore go back to the same period (1955–1913 B.C.), although the surviving examples of the series are somewhat later in date. Again, another B.M. text of the Seleucid period (321–64 B.C.) has an example exactly analogous to one which is more than a thousand years earlier. (2) The terminology for negative quantities (as such) can also be traced back to the earliest times. These things suggest that there was a continuous tradition all through the interval. (3) There is a problem in Part 2 about compound interest, in which it is required to find the period in which a capital sum accumulating at 20 per cent interest will double itself. The answer was given, but it was not clear how it would be arrived at. The mystery would now appear (p. 63) to be perfectly cleared up. It would be seen from exponential tables that the period is between three and four years; it is now shown that the working is consistent with the assumption that the time by which the period falls short of four years was obtained by the process of "linear interpolation".

Hydroxides and their Applications

Hydroxyde und Oxyhydrate
Von R. Fricke und G. F. Hüttig. (Handbuch der allgemeinen Chemie, herausgegeben von Paul Walden, Band 9). Unter Mitwirkung von H. Zocher und Hj. Saechtling. Pp. xx + 641. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1937.) 60 gold marks.

SINCE the time of Lavoisier, metallic oxides and their hydrates have played an important part in the development of chemistry, leading to the determination of atomic weights of elements by Berzelius and the enunciation of the periodic classification of elements by Mendeléeff and Lothar Meyer.

Metallic oxides either singly or in mixtures have been utilized as catalysts by Haber, Sabatier, Senderens, Bosch, Bergius, Mittasch, and others in ammonia synthesis, hydrogenation reactions and other industrial operations. In the chromatographic analysis for the separation of the plant pigments (Tswett), in the isolation of enzymes (Willstätter) and in the separation of carotinoids (Kuhn, Karrer), metallic oxides and hydroxides are being used. In the development of colloid science, sols and gels of oxides of metals and non-metals have taken a very prominent share. The adsorptive capacity of the silica, alumina and other oxides in the soil mainly controls the moisture retention and other properties of the soil.

Profs. Fricke and Hüttig, aided by Dr. Zocher and Dr. Saechtling, have done a useful piece of work in collecting and summarizing the literature on the subject in the work under notice. The book is divided into two main sections; in the first, the preparation and properties of almost all the oxides and their hydroxides (including those of rare earth metals) are described, along with the sols and gels obtainable from many of the oxides. The colloid chemistry of the well-known sols of the hydrated metallic oxides is fully discussed.

In the second section, a general account appears of the X-ray analysis of several oxides and hydrates, their ageing with time both in the solid state and in the colloidal condition, their vapour pressures, the velocity of their hydration, their solubility in alkalis, their thermochemical, magnetic and dielectric constants. The X-ray diagrams are well reproduced in the case of several hydroxides, and a summary of the crystalline characteristics and constants of seventeen hydroxides as derived from X-ray analysis is tabulated. The investigations on the phenomenon of ageing, including X-ray analysis, diffusion measurements, dialysis, potentiometric titrations, etc., are ably summarized. The hydration and dehydration of several oxides and hydroxides have been studied, notably by van Bemmelen, Zsigmondy, Bachmann, Willstätter, Hüttig, Fricke, Hackspill, Patrick, and others, and this important subject has been dealt with satisfactorily from different viewpoints. The thermochemical properties, specially the heat of hydration of numerous oxides and hydroxides, are tabulated. An adequate account of the magnetic properties of the metallic oxides and hydroxides and a brief summary of the dielectric constants of some hydroxide sols and their change with time form the last two chapters of the book.

As is expected in the case of handbooks of this type, there is an extensive bibliography of original papers. The subject matter is of interest not only from the academic point of view, but also because it has considerable industrial and practical use. Since Profs. Fricke and Hüttig and their collaborators have themselves made important contributions to the subject, the book is authoritative, and should prove useful to senior students, research workers, and teachers of chemistry.

N. R. DHAR.

My Friend Mr. Leakey

By J. B. S. Haldane. Pp. v+179. (London: The Cresset Press, Ltd., 1937.) 6*s*. net.

PROF. HALDANE here applies his imaginative and literary craftsmanship to the conquest of new worlds. His friend Mr. Leakey is the most lovable of magicians, with a finer sense of right and wrong than one had learned to expect of his profession, and with limitations—to his still exceptional powers—which are at once convincing and endearing. We can picture few greater joys than dinner with Mr. Leakey; should this note chance to reach Prof. Haldane's eye, perhaps he will relent and put the address of Mr. Leakey's flat (not 221*a* Baker Street, because it is quite near Haymarket) in the next edition—although we should not be surprised if it had to be in the next edition but one.

It must not be supposed that this book is a frivolous one. It is full of information of the kind that every active-minded reader wants: how to tell a caiman from a crocodile, the difference in display between the *Daily Mail* and the *Daily Herald*, the correlation between brain size and versatility, what a man-size—or rather woman-size—butterfly would look like, the physical properties of tungsten, the rivers and glaciers of London, and so on.

Of course we could not hope to understand all the ways of magicians and their friends. So perhaps we may never know why the rat-catching magnets were put in holes that had to be specially dug, instead of being put into the docks, which would surely have suited more than somewhat, nor why Mr. Leakey navigated south-eastward from London to get to India, when every Boy Scout knows that you should start off north of east, nor why he said that the beam wireless to Australia (the Rugby-Sydney axis as the other spell-binders would call it) went over Persia (shouldn't it be Iran?) when it really goes over Moscow, nor why Prof. Haldane chose "none were" instead of "none was" from the two forms which every Girl Guide knows to be permissible, nor why he said "Bortsch" when every Komsomol boy or girl knows that it sounds more like "Borstch".

We hope Prof. Haldane will write some more on afreets in Fleet Street.

Le milieu et la vie en commun des plantes

notions pratiques de phytosociologie. Par M.-A. Reynaud-Beauverie. (Encyclopédie biologique, Tome 14.) Pp. 238. (Paris: Paul Lechevalier, 1936.) 60 francs.

THIS comprehensive book is largely a compilation, based mainly on extracts from Braun-Blanquet's "Plant Sociology", as well as from other writings by the same author and those of Profs. J. Pavillard and P. Allorge. The book, which will be appreciated chiefly by French-speaking people, owing to the fact that "Plant Sociology" has not been translated into that language, is evidently intended to attract the intelligent amateur as well as those who are professionally interested in the subject.

Until comparatively recently, the activities of natural history societies have been mainly directed to collecting and naming specimens and compiling local lists of species. This has given rise to the popular view that "Le Botaniste est un Monsieur qui vient dans nos bois, dans nos prairies, cueille nos plus belles fleurs, les fait sécher entre deux feuilles de papier buvard où elles perdent leurs brillantes couleurs, et ensuite . . . il les insulte en latin". It is to be hoped that this book will help to broaden the outlook of, and suggest new lines of investigation to, those whose activities have hitherto been directed to the mere acquisition of collections as an end in itself. This should help to disperse the narrow conception of the nature of a botanist mentioned above.

All who are interested in the study of plants in their natural environment will find this book full of interest, but nowadays the subject is one which can be approached from so many angles that a good grounding in all branches of botany, and some knowledge of physics and chemistry, is desirable before the subject-matter of the book as a whole can be fully appreciated. That this is so will be realized from the diversity of subjects dealt with, which range from particulars of equipment for collecting plants to the influence of light, temperature and rainfall on vegetation, or the detection of nitrates in the soil. It is noteworthy that in the section dealing with the effect of light on vegetation the only methods described for measuring the light intensity in different habitats are those based on the use of sensitized paper. The application of the photo-electric cell for this purpose, which gives more accurate results, is not mentioned.

A fairly extensive bibliography is given at the end of each section of the book; but most of the references cited are French, although some English and German ones are included. The book ends with a short subject index.

With Camera and Notebook:

a Naturalist's Calendar (1938). Edited by Phyllis Barclay-Smith and Rudolf Zimmermann. Pp. 60. (London: M. C. Forrester, 1937.) 3*s*. 6*d*. net.

A CALENDAR which will sustain interest and give pleasure throughout the year is not easy to find; Shakespearian quotations have become stale, and the Aberdeen joke is satiating after the first hundred. Perhaps the nearest approach to general interest has been achieved by the landscape calendars published by various newspapers, but the idea of a naturalists' calendar on the present scale is a new and excellent one. Each week has its photograph, reproduced by fine-meshed half-tone block about 5 inches by 6 inches in surface, and its appropriate news item, and the fact that the photographers include Seton Gordon, Mortimer Batten, C. W. R. Knight, J. D. Rattar and K. Herschel, is a guarantee of the value of the pictures, scientifically and æsthetically. They are mostly of mammals, birds, insects and wild flowers, and although a few are from Continental examples all the species illustrated are members of the British fauna. Miss Barclay-Smith and Rudolf Zimmermann of Dresden are to be congratulated on the beauty and interest of the photographs they have chosen. The stranded jelly-fish, mistakenly identified as *Aurelia aurita*, appears to be an *Æquorea*.

The Sense of Hearing in Fish*

By Prof. K. von Frisch, University of Munich

THERE is an old dispute as to whether fish are able to hear or not. It has seemed improbable that they can. Three main reasons have been brought forward against it.

(1) A biological reason: most fish seem to be dumb; a sense of hearing would therefore not be of biological significance for them.

(2) An anatomical reason: the inner ear of mammals has two main functions. It is the organ of equilibrium and the organ of hearing. Perception of equilibrium is the function of the utriculus and the semicircular canals. It is not yet clear if the sacculus of mammals has to do with equilibrium or with hearing. At the sacculus we find the cochlea; it is generally supposed that the cochlea alone is the organ of hearing. Comparative anatomy shows that there is no cochlea in the inner ear of fish. We find only a cavity of the sacculus, the lagena (Fig. 1, *L*), which is supplied with a stone and macula just like the sacculus (*S*) and utriculus (*U*). It has been suggested that fish cannot hear because the organ of hearing is not yet developed.

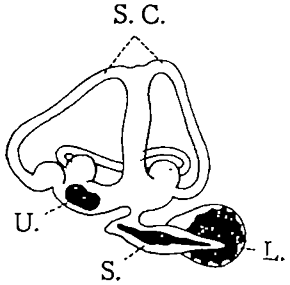

FIG. 1.
THE LABYRINTH OF A MINNOW. *U* = UTRICULUS; *S.C.* = SEMICIRCULAR CANALS; *S* = SACCULUS; *L* = LAGENA.

(3) The third reason against the acceptance of a sense of hearing in fish was a physiological one. Many investigators tried to clear up the matter by making experiments, but they could not observe any reaction of fish to sound. But on this point there is no agreement. For example, American investigators, especially Prof. Parker and his collaborators, made experiments with various fish with positive results. Opponents, especially in Germany, could not confirm it. It was argued that if there is a reaction to sound it would be a reaction to the movement of water and not to sound vibration—it would not be true hearing.

So the question arises: What is hearing? I think that, in vertebrates, it is not difficult to define it. Human beings can perceive very loud sounds by means of the skin and by means of the inner ear. Perception through the skin we call feeling; perception through the inner ear we call hearing. In all vertebrates the inner ear is a homologous organ. We should only speak about 'hearing' in the case of the perception of sound vibrations by means of the inner ear in vertebrates.

But the first question must be: Is there a reaction to sounds in fish? There was no agreement on this point. Many observers could not see any reactions to whistling, or to notes from a violin, or to the voice of a singer, and so on. But that is not astonishing. The voice of a singer or the sound of a violin or whistle is not of the slightest biological significance for fish. We should not wonder, therefore, if they do not react to it.

I thought, however, it might be possible to give a biological significance to sounds. If we whistle every time when we give food to the fish, then whistling acquires a biological significance, because the food is announced by it. First I performed the experiment in the following manner. I had a little catfish, *Amiurus nebulosus*, in an aquarium. It lay mostly in an earthenware pipe put on the bottom of the aquarium. The fish was blind, both eyes having been removed, and so it could not see what happened. It got the food from a glass feeding-rod. When the food was brought near the opening of the pipe the fish perceived the meat by means of its chemical sense, came out and swallowed the food. Then, every time I gave it food, I whistled with my lips. Thus I tried to train the fish to the whistling. After some days the fish came out when I whistled before I put the feeding-rod into the water, swam upwards and sought for the food; and always after that it could be called out by soft whistling not only from nearby but also from a considerable distance, for example, from the other side of a large room.

Later these experiments were continued by my collaborator, Dr. Stetter. He used various kinds of fish. The best results were given by our little minnows (*Phoxinus lævis*), and therefore they have been studied very thoroughly. To produce sounds tuning forks were generally used for low sounds and whistles for the higher ones. The sense of sight was eliminated by removal of the eyes. Then the fish was trained to a certain sound by four to five training feedings daily. After a few days the fish gives a very typical reaction to sound. The kind of reaction varies from individual to individual. When the sound is given, some fish dive down and snap for food on the bottom, others go up and snap on the surface, others stop and snap vigorously on whatever spot they may be, but all snap and seek for food because they are accustomed to get the food when the sound is given. After a few seconds we put the feeding-rod into the water; the fish gets the food, and so the training is continued.

---

* Substance of a lecture delivered at University College, London, on March 4, 1937.

There is not the slightest doubt that there are clear reactions to sound. Further experiments by Dr. Stetter gave a great many results. It seems to me that three of them are of special interest.

Dr. Stetter tried to train fish to very low and to very high sounds, and so to find out the limits of the sense of hearing. The upper limit in minnows is between D^5 and A^5 (about 5,000–7,000 vibrations a second). Training to higher sounds is without results. There are slight individual differences; but there is a far greater difference between various species of fishes. Thus *Amiurus* gave positive results up to 13,000 vibrations a second. This is about the same upper limit as in human beings. Dr. Stetter was unable to find a lower limit. The lowest tuning fork, C_2 (frequency 16), gave good results.

A second result concerns the acuteness of the sense of hearing. A minnow was trained to E^2 (frequency 660). Then the sound of the whistle was diminished gradually to a very low intensity. The aquarium was put on a table in a long corridor and the soft whistle was given from farther and farther away in a series of experiments until reactions could no longer be obtained. Reactions could be obtained from a distance of about 200 feet. We ourselves could hear the whistle from that distance only as a very weak sound. But it is difficult to understand what this means, because we do not know to what extent the sound is weakened on entering the water. We therefore brought a large aquarium to the same spot and one of our students dived down and was tested in just the same manner as the fish. The experiment showed that our best fishes could hear as well as men in the aquarium, or even a little better than men. It was very surprising to us.

The third result concerns the discrimination of sounds. It is possible to prove that minnows can distinguish between different sounds. The following method was employed. A fish is trained to a certain sound, that is, the feeding sound. When there is a good feeding reaction, we introduce another sound one or two octaves higher or lower than the feeding sound. But at this sound no food is given, and if the fish begins to snap and seek for food, it is punished by a light blow with a glass rod. This other sound we call the warning sound, because it means a punishment. After some time of training, the fish gives the feeding reaction only to the feeding sound; to the warning sound it gives no reaction, or even a very distinct flight reaction to avoid the punishing blow. Now the interval between the two sounds can be gradually decreased, and thus we can find out what interval can be distinguished. Most fishes can easily be trained to distinguish between two sounds at an interval of one octave. The best fish could distinguish perfectly between the two sounds of a minor third, D^1/F^1 (frequencies 290 and 345).

During 1936, Dr. Wohlfahrt in our laboratory was able to improve these results by employing a new method. In the experiments of Dr. Stetter there was always a period of at least a quarter of an hour between the feeding sound and the warning sound. The fish, therefore, had to keep the sound in mind and decide by memory. It was clear from these experiments that the fish has some sense of absolute hearing—but not a very good one. Wohlfahrt gave short sounds so that they immediately followed one another, just like a trill. In this way he was able to show that minnows are able to distinguish even a half-tone interval.

Judging from all these results, it is very probable that there is a true sense of hearing in fishes. To be certain we must seek for the organ of perception.

Experiments have been published by Prof. Parker and his collaborators indicating that the inner ear especially has to do with hearing in fishes. Some observations seemed to show that the sacculus especially, or the lagena, would be the seat of the sense of hearing. But the results were not very convincing, because the methods employed to eliminate the sacculus and the lagena were not satisfactory. The method of training the fishes to sound, combined with careful operations, promised a clear result.

I removed various parts of the labyrinth in minnows. I tried first to remove the utriculus and the ampullæ and to leave the sacculus and the lagena intact. There is no difficulty in doing this. To perform the operation the fish is narcotized by means of a 0·5 per cent solution of urethane. As soon as the fish recovers from the narcotic we find that it has completely lost its sense of equilibrium. It lies on one side on the bottom of the aquarium, and when it swims it turns over and curves the body in a peculiar manner. Nevertheless, it is possible to train such fish to sounds as easily as normal ones. Training can be carried out in the same manner, in the same time, and within the same limits as in the case of normal fishes. There is not the slightest sign that the utriculus and the ampullæ have anything to do with the sense of hearing. They are only organs of equilibrium. It is more difficult to remove the sacculus and the lagena; but I have succeeded in doing this. It was very surprising to see that such fish, with both sacculi and lagenæ and their large otoliths removed, swim in perfect equilibrium. But it is impossible to train them to sounds. Generally I did with each of them more than a hundred training feedings, but the fish gave no reactions to the sounds. Normal fish or fish only operated upon on one side gave reactions after five to fifteen training feedings. I carried out the experiment also in the following manner. I trained a normal fish to a sound. Then it was operated on on one side. The reaction was as clear as before. The fish was operated on on the other side, and then it was never possible to get any reactions.

All this applies only to sounds higher than *C* (frequency 130). The fish without sacculus and lagena can be trained to low sounds, if they are loud enough. It can even distinguish between different sounds in the low region as well as normal fish. The low sounds are perceived as well as before, even if the whole labyrinth is taken away or if the sense organs of the lateral line, too, are fully destroyed. We can therefore assume that the low sounds are perceived through the skin.

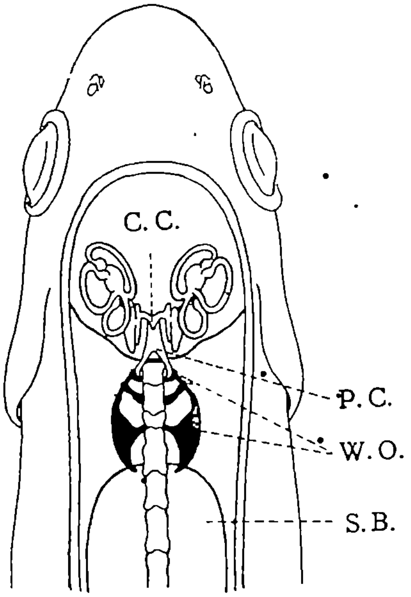

Fig. 2.

C.C. = CROSS CANAL, CONNECTING THE SACCULI WITH ONE ANOTHER; *P.C.* = POSTERIOR CAVITY; *W.O.* = WEBERIAN OSSICLES; *S.B.* = SWIM BLADDER.

From special experiments it can be concluded that the lowest sounds are perceived only with the skin, low sounds from frequency 25 up to about 130 with the skin *and* with the inner ear, and all the middle high and very high sounds from about frequency 130 up to the upper limit only with the labyrinth. That is more or less the same as in human beings.

It is stated above that minnows, in the region of middle high sounds, can distinguish between different sounds even when there is an interval of only half a tone. Now we know that these sounds are perceived by the sacculus and lagena. Thus we find that there is a remarkable ability to distinguish between different sounds in the fish labyrinth, in spite of the lack of a cochlea and therefore in the absence of a membrana basilaris. The function of the cochlea and of the membrana basilaris in higher vertebrates may be to improve the discrimination of sounds to the high degree known in man.

Certain anatomical facts are very important for understanding the acuteness of the sense of hearing in minnows. In minnows, as in all Cyprinids, there is a connexion between the labyrinth and the swim bladder by means of the Weberian ossicles. The sacculus of the right and left labyrinths are connected with one another by a cross canal (Fig. 2, *C.C.*) with a posterior cavity behind the labyrinth (*P.C.*) with one opening on each side. The opening is closed by a little bone connected with other bones by articulation (*W.O.*), the last of which is fixed to the anterior end of the swim bladder (*S.B.*). Sound vibrations in water must be transmitted to the swim bladder, from the swim bladder by means of the little bones to the cavity, from there to the cross canal and thence to the sacculus. Now it is very interesting that the shape of the otolith of the sacculus seems to make it suitable to take up the vibrations coming from the cross canal—a fact first recognized by the Dutch worker, Prof. de Burlet, in *Amiurus*.

We want to know, however, whether this connexion is necessary for sound perception. Consequently I took away the swim bladder through an incision in the ventral body wall of the minnow. I closed the wound by a suture and after recovering the minnows could be trained to sounds as before. But the acuteness of the sense of hearing was very much reduced. It seemed from these experiments that this connexion between the swim bladder and the sacculus might increase the acuteness of hearing.

If that were true, we should find a sense of hearing very well developed in all fishes possessing Weberian ossicles. All five species of Cyprinids which have been trained for sounds in our laboratory up to now have a very well-developed sense of hearing. The same is true for *Amiurus*, which belongs to the Silurids. They have Weberian ossicles too. On the other hand, in families having no connexion between the swim bladder and the inner ear, the sense of hearing is very poorly developed. We tried to train for sounds pike, perch, trout, eels and others. Some of them gave no results at all, others could be trained, but the sounds had to be made much louder than for *Amiurus* or for minnows, and the high sounds were never perceived.

Besides Cyprinids and Silurids there are two other families possessing Weberian ossicles: Characinidæ and Gymnotidæ. We trained a *Gymnotus* and some Characinidæ and found a well-developed sense of hearing in all these fish.

Now I wish to direct attention to a peculiar anatomical fact often mentioned in books of comparative anatomy, but never understood. In the Mormyrids, a family of African fish, there is a gas bladder on each side of the skull connected directly with the sacculus. In early embryological stages it is developed as a double cavity of the swim bladder, growing into the head. Later the connexion with the swim bladder is lost by degeneration and the two small air bladders lie completely separated in the skull. I thought that the function of these little air bladders might be the same as that of the big air bladder in minnows and other fishes possessing Weberian ossicles. Sound vibrations reaching the air bladders should cause vibration of them. In this case the stimulus can be transmitted directly to the sacculus, and therefore Weberian ossicles are not necessary. If that is true, we should expect a very well-developed sense of hearing in Mormyrids, although they do not have Weberian ossicles. It was rather difficult to get living Mormyridæ, and we looked for them for several years without success. But finally we got them. We began to train them for sounds with much interest, and we found with satisfaction that they could hear just as well as our best minnows. The anatomical peculiarities of these interesting labyrinths are now being studied in our laboratory.

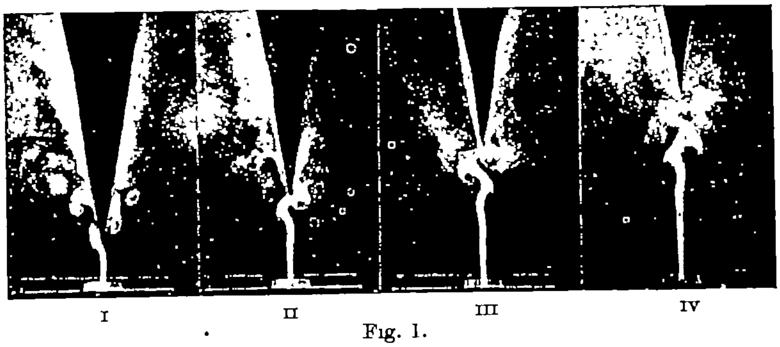
It may well be asked for what purpose fishes are able to hear so well in silent water. It is not true that all fish are dumb. We know many species of sound-producing fish. There may be many more species of sound-producing fishes not yet known. Some years ago, Dr. Dykgraaf in our laboratory found out that minnows, too, are sound-producing fishes. If they are excited, a soft piping comes from the aquarium. The noise is very soft, but knowing the acuteness of the sense of hearing, we may be sure that it can be heard by the minnows. It is interesting that the production of sound by so well known a fish should have been overlooked for so long. There may be much to discover in the future about the language of fishes.

Organ Pipes and Edge Tones

By Dr. G. Burniston Brown, University College, London

ORGAN pipes have long been a favourite theme for the musician and for the physicist, but they are very far from being the simple structures idealized in the text-books. One source of complication in the actual organ pipe is the behaviour of the air stream at the mouth, which results, for example, in the note produced by blowing in the normal manner being higher in pitch than the natural note of the pipe considered as a resonator.

Another problem connected with the phenomena at the lip is the variation of pitch with the pressure of the air supply: in fact, one of the most puzzling features of the behaviour of organ pipes is the curious succession of tones which is evoked when they are underblown, that is to say, when the air is admitted with slowly increasing pressure. The subject has been investigated by Rayleigh[1], Lutz[2], Gunnaiya and Subrahmaniam[3] and others, and although it had been suggested that the pipe tones were initiated by edge tones, no observations of their relationship were made. A recent investigation has helped to make the production of these tones clearer by showing that they are intimately connected with the general problem of edge tones.

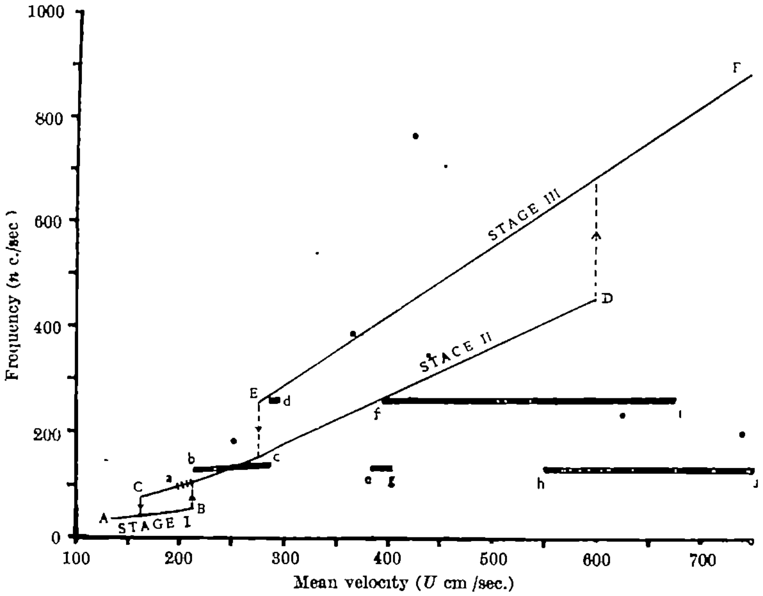


I II III IV

Fig. 1.

STAGES OF VORTEX FORMATION WHEN AIR IMPINGES ON A WEDGE.

An examination of edge tones[4] has shown that, when a jet of air impinges on a wedge, four distinct types or stages of vortex formation may occur. These four stages are illustrated in Fig. 1 for the case where the velocity of the jet is constant and the heights of the wedge are such that the frequency is the same in each stage. The four stages can also be obtained in succession when the height of the wedge is kept constant and the velocity of the jet is increased: the relation between the frequency n and the mean velocity U in such a case is shown by the thin line in Fig. 2. The frequency rises from A to B (Stage 1), then jumps suddenly to Stage II, continuing to rise until the point D, where another jump to Stage III occurs. The jump to Stage IV is not shown. If the velocity is decreased, the jumps to lower frequencies at C and E do not take place at the same velocity as the jumps to higher frequencies at B and D. When the velocity of the jet is above 500 cm./sec., Stage I may continue and occur simultaneously with each of the other stages.



——, Free edge tones; ▬, organ pipe tones; ++++, organ pipe edge tones.

Fig. 2.

OPEN WOOD DIAPASON. FUNDAMENTAL 130 C./SEC.; UNDERBLOWN OCTAVE, 264 C./SEC.

The organ pipe used was an open wood diapason of length 113·5 cm., rectangular in cross-section, 4·7 cm. × 5·8 cm., with a flue of length 4·7 cm. and breadth approximately 0·175 cm. (much nicking), and the cut-up was 1·6 cm., giving a fundamental tone of 130 c./sec. Air impregnated with cigarette smoke was used and the resulting vortex motion examined stroboscopically. The results obtained are shown by the thick lines in Fig. 2.

The free edge tones for a jet of the same width and wedge height as in the pipe were also observed and these produced the thin line *ABCDEF* already described. They are audible when U is above about 500 cm./sec.

The tones emitted by the pipe correspond exactly with those found by Rayleigh. His account of his experiments with an open 2 ft. metal pipe in which the pressure was slowly decreased is reproduced below:

Rayleigh	Diagram
"About this point the octave of the normal note is heard	*i* + *j*
after which the normal note itself disappears	*h*
The normal note reappears, the octave continuing.	*g*
The octave goes	*f*
and then the normal note	*e*
after which there is silence.	*ed*
Octave comes in again,	*d*
and then the normal note, at a pitch which falls from considerably above to a little below the natural pitch.	
At the lowest pressures the normal note is unaccompanied by the octave"	*cb*

In order to explain the mechanism of the production of this sequence, it is more convenient to consider what occurs with increasing velocity. In the pipe used, the construction of the block and lower lip was such that the jet of air is directed outwards and does not encounter the edge until its velocity is 200 cm./sec. Consequently Stage I is unstable and edge tone oscillation commences at a (Stage II): when this reaches a frequency of n = 100 c./sec., oscillation is set up in the pipe and the edge tone changes suddenly to n = 126 c./sec. at b, and this frequency is feebly emitted by the pipe. The combination of the pressure changes in the pipe, and those in the wake of the vortices entering the pipe (which according to my theory are the cause of free edge tone production) result in the frequency of pipe and edge tone rising continually and slowly together to n = 136 c./sec. at c, (U = 290 cm./sec.). The pressure changes in the pipe are not sufficient to affect the edge tone any further and the sound ceases. But it happens that Stage III in the free edge tones at U = 290 cm./sec. has a frequency very close to the octave, and this gives rise, for a short interval, to a very feeble octave note at d.

The construction of the block and lip now causes the jet to pass just *inside* the edge, and silence ensues, together with absence of edge tone oscillation, until the velocity reaches 380 cm./sec. At this velocity a disturbance passing up the jet and striking the edge would produce a frequency of nearly double the fundamental, and pressure variation of this frequency being reinforced by resonance, the note is maintained in spite of the fact that the jet does not strike the edge centrally. If the velocity is increased very slowly, however, the fundamental is elicited first at *e*. This presumably is due to the fact that the fundamental frequency, $n = 130$ c./sec., is *less* than half the octave, $n = 264$ c./sec., so that the edge tone reaches double the fundamental of the pipe before reaching equality with the octave. When the octave sounds at *f*, the pipe takes complete control and the frequency remains constant (Stage II). When the velocity reaches 550 cm./sec. at *h*, the real fundamental of the pipe begins to sound and the jet oscillates as a whole from side to side (Stage I). The octave note can still be heard but disappears at *i*. The occurrence of Stage I at such a high velocity is quite impossible without a resonator.

It seems, then, that edge tones are responsible for the initiation of the vibrations in musical wind instruments of the organ type, and that even the details of the complex initial phenomena can be accounted for adequately.

Scientific Centenaries in 1938

By Engineer Captain Edgar C. Smith, O.B.E., R.N.

THE scientific centenaries which occur this year are of wide and varied interest. They include the tercentenary of the printing at Amsterdam of Galileo's great work, the "Dialogues of the Two Sciences of Mechanics and Motion", and of the birth of the Scottish mathematician James Gregory; the bicentenary of the death of Boerhaave, the famous Dutch physician and chemist, and the bicentenary of the birth of Sir William Herschel; and the centenaries of the death of Dulong, the French chemist and physicist, and of Nathaniel Bowditch, the American mathematician and astronomer, and also the centenaries of the birth of Sir William Perkin, Ernest Solvay, Cleveland Abbe, George James Symons, Pietro Tacchini and of Count Zeppelin. The year 1738 also saw the publication of Daniel Bernoulli's "Hydrodynamics", while the year 1838 witnessed, first the inauguration of trans-Atlantic steam navigation, and secondly, the opening of the whole of the railway line from London to Birmingham, constructed by Robert Stephenson.

James Gregory (1638–75) was the younger brother of David Gregory (1627–1720). Together they founded the scientific fame of a family of men of science. When about twenty-four years of age, James published his "Optica Promota", containing the description of the Gregorian reflecting telescope, and suggestions for utilizing the transits of the minor planets for accurately determining the solar parallax. He studied at Padua, had a controversy with Huygens, corresponded with Newton, and in 1668 was made professor of mathematics in the University of St. Andrews, and in 1674 professor of mathematics at Edinburgh. In October 1675, while showing the satellites of Jupiter to his students, he was struck blind, and he died a few days later. An English contemporary of Gregory was Edward Bernard (1638–97), who was Wren's successor in the Savilian chair of astronomy at Oxford. He held this post from 1673 until 1691, when he was succeeded by David Gregory, the nephew of James. Bernard was a clergyman, having graduated from St. John's College, Oxford. His sole recorded astronomical observation is that of the solar eclipse of July 2, 1684, but he was an indefatigable collector of mathematical manuscripts. The year 1638 also saw the birth of the French botanist Pierre Magnol (1638–1715) of Montpellier. Both botanist and physician, he held the chair of medicine in his native town and was physician to Louis XIV. In 1705 he visited Paris and was admitted to the Academy of Sciences, but his heart was in his botanic garden at Montpellier. The genus *Magnolia* was named after him by his countryman Plumier.

Among the men of science, besides Boerhaave, who died in 1738, were Benedict de Maillet, the French geologist, and Richard Helsham, the Irish natural philosopher. De Maillet, who was born in 1656, came of a noble family of Lorraine. At thirty-three years of age, he was made consul-general in Egypt, and he held this position for fifteen years. He was also consul-general at Leghorn, and travelled in the Near East. He left a description of Egypt and a geological work in which he regarded all the rocks of the earth as marine deposits. The work was written in 1715–16, but was not published until some years after his death, when it appeared under the title "Telliamed", an anagram of de Maillet. It contains six imaginary dialogues between an Indian philosopher, Telliamed, and a French missionary. After reviewing this work, von Zittel concluded that "if we except the concluding chapters, the *Telliamed* far outshines other geological writings of the eighteenth century in its wealth of observed facts, its daring originality and its charm of style". Helsham, who was born about 1682, spent nearly the whole of his life in Dublin. A fellow of Trinity College, he lectured on mathematics and was the first to be appointed to the professorship of natural philosophy founded out of the funds left by the merchant Erasmus Smith. Helsham was a great friend of Dean Swift.

Hermann Boerhaave, who was born on December 21, 1668, and died on September 23, 1738, has been referred to as the most celebrated physician of the eighteenth century. He was equally at home in theology, music, botany and chemistry. He extended the botanic garden at Leyden, and in 1718 became professor of chemistry in the University. His well-known work "Elementa Chemiæ" was translated into several European languages. He was a foreign member of both the Paris Academy of Sciences and of the Royal Society. He is buried in St. Peter's, Leyden.

The bicentenary of the birth of Sir William Herschel, who was born on November 15, 1738, will recall the name of one of the greatest of astronomical discoverers. For fifty years his aim was to obtain "a knowledge of the construction of the heavens". In her "History of Astronomy" Miss Clerke wrote: "The rise of Herschel was the one conspicuous anomaly in the astronomical history of the eighteenth century. It proved decisive of the course of events in the nineteenth. It was unexplained by anything that had gone before; yet all that came after hinged upon it. It gave a new direction to effort; it lent a fresh impulse to thought. It opened a channel for the widespread public interest which was gathering towards astronomical subjects to flow in". The year 1738 also saw the birth of the famous French hydrographer, Charles Pierre Claret, Comte de Fleurieu (1738–1810), who had been entrusted with the testing of the marine chronometers of Berthoud, and who organized the expeditions of La Perouse and D'Entrecasteaux; the French aeronaut Jean-Pierre Blanchard (1738–1809), who with Dr. John Jeffries on January 7, 1785, made the first crossing of the Channel by balloon; the German mineralogist Franz Ludwig von Cancrin (1738–1816), who directed the salt mines of Russia and published a work in thirteen volumes on mining; and also of Christophe-Philippe Oberkampf (1738–1815), who added to the wealth of France by introducing the art of calico printing. Born in Germany, his life's work was done in France, and he received a decoration of the Legion of Honour from Napoleon.

Of the men of science who died a century ago, passing mention may be made of Samuel Woodward (1790–1838), the Norwich bank clerk who published a book containing a list of all British fossils then known; Thomas Andrew Knight (1758–1838), the horticulturist whose efforts were directed to the improvement of fruit trees; Charles Tennant (1768–1838), who in 1799 patented a process for the production of bleaching powder, and in 1800 founded the great chemical works at St. Rollox, Glasgow; Bernard Courtois (1777–1838), the discoverer of iodine; and Pierre-Louis Dulong (1785–1838), a professor at the Paris Ecole Polytechnique and one of the secretaries of the Paris Academy of Sciences, who with Alexis-Thérèse Petit (1791–1820) made important investigations in heat and chemistry. Nathaniel Bowditch, who also died in 1838, began life in a ship-chandler's shop, but rose to be president of the American Academy of Arts and Sciences. His great work was his translation, with a commentary, of Laplace's "Mécanique Céleste", which Simon Newcomb said "made an epoch in American science by bringing the great work of Laplace down to the reach of the best American students of his time". His countryman, Colonel John Stevens (1749–1838), a pioneer of steam transport, constructed the first steam boat driven by a screw propeller, and with his sons did much to further both railways and steam navigation.

The work of this last group of men belongs to the early part of the nineteenth century, just when the value of scientific studies was becoming increasingly appreciated, when technical schools were being opened and physical and chemical laboratories were being established. The seed sown in these laboratories was to bear a fruitful harvest, and no industry benefited more from their establishment than the chemical industry. A century ago, Liebig was making the Giessen laboratory the Mecca of chemical students, and Wöhler had already begun teaching at Göttingen. One of Liebig's students was Hofmann, who came to London in 1845 to teach at the old Royal College of Chemistry, in which Sir William Perkin—whose centenary occurs in March—was studying when he made the discovery which laid the foundation of the coal-tar colour industry. Perkin was only eighteen years of age when he discovered aniline mauve and only nineteen when he started its manufacture at Greenford Green, near Harrow. Fifty years later, he was the central figure of a great international gathering which assembled to celebrate the jubilee of his discovery. The agricultural chemist Robert Warington (1838–1907) also owed something to Hofmann. Warington worked under both Lawes and Frankland, and for many years took part in the work at Rothamsted. Other chemists born a century ago were Wladimir Markownikoff (1838–1904), whose work was of great importance to the Caucasian petroleum industry; Ernest Solvay (1838–1922) whose patent of 1863 led to a revolution in the manufacture of common soda, and François Lecoq de Boisbaudran (1838–1912), who first isolated gallium and received the Davy Medal of the Royal Society.

Passing from the ranks of the chemists to those of the physicists and astronomers, two of the outstanding meteorologists of last century were George James Symons (1838–1900) and Cleveland Abbe (1838–1916). Symons was the founder of the British Rainfall Organisation and of *Symons' Meteorological Magazine*, now the *Meteorological Magazine*. He was twice president of the Royal Meteorological Society, and every two years his name is recalled by the award of the Symons Medal founded to his memory. Abbe at first was an astronomer, but from the passing by the United States Congress of the Weather Bureau Act in 1870 until his death he was the leading meteorologist in his country. Among Abbe's countrymen were James Craig Watson (1838–80), director of the Ann Arbor Observatory, who discovered twenty-two minor planets and wrote a standard text-book on theoretical astronomy, and George William Hill (1838–1914), who in 1909 was awarded the Copley Medal of the Royal Society for his researches on the theory of the moon. Hill's career was bound up with the "American Ephemeris and Nautical Almanac". Two other astronomers born at the same time were Pietro Tacchini (1838–1905), the successor of Secchi at the observatory of the College Romano and the organizer of the Meteorological and Geodynamical Institute of Rome, and Arthur Auwers (1838–1915), whose work was mainly concerned with the fundamental systems of star places and proper motion. His new "Reduction of Bradley's Observations" occupied him from 1866 until 1876. In 1912, the fiftieth anniversary of his doctor's degree, the Berlin Academy of Sciences instituted the Bradley Medal and British astronomers presented Auwers with a copy of the portrait of Bradley by J. Richardson.

To these names may be added those of Ernst Mach (1838–1916) of Prague and Vienna, whose researches in mechanics led him to study by means of photography the motion of a bullet through air; Karl Selim Lemström (1838–1904) of Helsingfors, who made researches on atmospheric electricity, and the effect of electricity on plants; Carl-Louis Schwendler (1838–82), an electrical engineer of German nationality who worked many years with the telegraph department of India; and General Charles Webber (1838–1904), an officer of the Royal Engineers, who was also an expert in telegraphy and assisted the Post Office to organize its telegraph department and with Sir Francis Bolton in 1871 founded the Society of Telegraph Engineers, now the Institution of Electrical Engineers. The geologists, Sir William Boyd Dawkins, Ferdinand Stoliczka and Alfred Elis Törnebohm, were also born in 1838, as was Sir Walter Lawry Buller, the New Zealand ornithologist, to whom there is a tablet in St. Paul's Cathedral.

Of the many inventors and engineers born in 1838 who in one way or another made their mark, Samson Fox (1838–1903) was the inventor of the corrugated flue for boilers which was adopted in all classes of steamships, and a pioneer of the acetylene industry; Peter Brotherhood (1838–1902) was a pioneer in the construction of high-pressure air compressors and of high-speed steam engines; Charles Edward Emery (1838–98) did important work in marine engineering and was responsible for the construction of a central station for house-to-house distribution of steam; Henry Spencer Palmer (1838–1893), a British military engineer, was a geodicist of note and designed the Hong Kong Observatory as well as public works in Japan; William Henry Maw (1838–1924) was president of the Institution of Civil Engineers and of the Royal Astronomical Society and for more than fifty years editor of *Engineering*, while William Cawthorne Unwin (1838–1933) was, in the words of Lord Balfour, "one whose name was honoured wherever engineering was studied in English-speaking lands". Count Zeppelin, who has already been mentioned, was born on July 8, 1838, and died on March 8, 1917, eighteen years after he had built his first airship.

Of all the achievements of engineers in 1838 the place of honour belongs to the men who promoted the plans and built the ships for trans-Atlantic steam navigation. Four steamships, the *Sirius*, *Royal William*, the *Liverpool* and the *Great Western*, made passages between England and New York in 1838, but it was the performances of Brunel's *Great Western*—the *Queen Mary* of her day—that opened men's eyes to the possibilities of steam navigation. The centenary of her first voyage will be commemorated in various ways, and a special exhibition in connexion with the event is being arranged at the Science Museum, South Kensington.

Obituary Notices

Dr. G. A. Boulenger, F.R.S.

GEORGE ALBERT BOULENGER, who died on November 23 at St. Malo at the age of seventy-nine years, was one of the most distinguished of a line of descriptive biologists who have brought fame to the British Museum during the past century.

Born at Brussels on October 19, 1858, the son of Gustave Boulenger, a notary of Mons, Boulenger early exhibited a passion for natural history, and particularly for reptiles and batrachians. While still studying at the University of his native city, he was already engaged in the determination of reptiles, batrachians and fishes in the Natural History Museum at Brussels, and in 1880 he was appointed assistant naturalist in that institution. This appointment he very soon resigned, and came to London at the invitation of Dr. Günther, then keeper of zoology in the British Museum, in order to prepare a new catalogue of the batrachians in the national collection. In the words of Günther, "this proved to be the beginning of a long, most meritorious and beneficial service".

In 1882 Boulenger was appointed a first-class assistant in the Department of Zoology, a position which he held until his retirement in 1920. One of his first duties was the supervision of the removal of the spirit collections from Bloomsbury to South Kensington.

Gifted with tremendous energy, an extremely methodical mind, and a memory that was little short of amazing, Boulenger accomplished a vast amount of scientific work during his forty years at the museum. From 1882 until 1920 a continuous stream of papers flowed from his pen. A list of his herpetological and ichthyological contributions published by the Zoological Society of Belgium in 1921 includes no less than 875 papers in scientific journals and other periodicals, and takes no account of numerous articles of a more popular nature in the *Field*, *Country Life*, etc. His most important contributions to science, however, were the elaborate and detailed monographs, mostly published by the British Museum, which remain to this day the solid foundation of all modern systematic work on the groups of animals concerned. Of these, mention may be made of the "Catalogue of Batrachians . . ." (2 vols., 1882), "Catalogue of Lizards . . ." (3 vols., 1885–87), "Catalogue of the Chelonians, Rhynchocephalians, and Crocodiles . . ." (1889), "Catalogue of the Snakes . . ." (3 vols., 1893–96), "Monograph of the Lacertidæ" (1920), all published by the Museum; the volume on reptiles and batrachians in the Fauna of British India series (1890); and the monograph on the tailless batrachians of Europe, published by the Ray Society (1897–98). The first (and only) volume of a new edition of the "Catalogue of Fishes . . ." (1895), covering several important Percoid families; "Les Poissons du Bassin du Congo" (1901); "Fishes of the Nile" (2 vols., 1907); the systematic section on the Teleostei in the "Cambridge Natural History" (1910); and "Catalogue of the Fresh-water Fishes of Africa . . ." (4 vols., 1909–15); are perhaps the most valuable of his major contributions to systematic ichthyology, and are veritable monuments of painstaking research. The Museum "catalogues" are worthy of special mention, since they represent complete revisions of large groups of animals from all over the world, and, for the most part, they are to-day still the only complete revisions of the groups concerned. That, in addition to this prodigious output of scientific work, Boulenger was able to find time to prepare the sections dealing with reptiles, batrachians and fishes in the *Zoological Record* every year from 1880 to 1904, is a tribute to his amazing and indefatigable energy.

Boulenger's study of the rich collections of freshwater fishes obtained in the Congo basin about 1898, and of those collected during the Egyptian Government's survey of the Nile, directed his special attention to the fishes of the African continent, and these remained his principal interest during the remainder of his museum career. Determined to use every effort to fill the gaps in the national collection, he encouraged travellers and residents in various parts of Africa to send home specimens, with the result that the British Museum now possesses a collection of African freshwater fishes unparalleled in the world. His intensive study of these fishes led him to formulate certain general conclusions concerning the origin and distribution of the African fish-fauna, and his views were ably summarized in his presidential address to Section D (Zoology) of the British Association in 1905. The study of this illuminating address may be recommended to those of the younger school of zoologists to whom systematic zoology is a convenient method of cataloguing, and something quite apart from modern conceptions of science.

On his retirement in 1920, herpetology and ichthyology were almost entirely abandoned in favour of another abiding interest. Long attached to the study of flowers, and particularly of roses, he had spent many of his vacations during his later years at the Museum in visiting various European countries in search of data and specimens. He now became attached to the Botanical Gardens in Brussels, where he undertook the study of the fine series of roses in the herbarium of François Crépin. He was engaged upon a monograph of the European roses at the time of his death, and two volumes had already been published under the title of "Les Roses d'Europe de l'Herbier Crépin".

Boulenger's work was widely recognized by corresponding or honorary membership of many learned societies both at home and abroad. He was elected a fellow of the Royal Society in 1894, and served on the Council. He was also a member of the Council of the Zoological Society nearly continuously from 1893 until 1911, and was for several years a vice-president. He was a doctor *honoris causa* of Louvain, Giessen and St. Andrews, and received a silver medal from the Société d'Acclimatation de France. In 1935, the American Society of Ichthyologists and Herpetologists elected him as its first honorary member, and in 1937 the country of his birth conferred upon him the Order of Leopold, an honour which gave him great pleasure and of which he was justly proud.

The writer of this notice did not come into contact with Boulenger until shortly after his retirement, but he cherishes the memory of several informal talks and discussions. The kindness and courtesy shown to a beginner by one who was the acknowledged master of his subject will always be remembered, and played no small part in the writer's education in systematic ichthyology.

A naturalized Englishman, Boulenger married Emilie, daughter of Charles Heyman of Brussels, who died in 1936. He leaves three sons, two of whom have adopted zoology as a profession. J. R. N.

Prof. A. J. Ewart, F.R.S.

ALFRED JAMES EWART, who died suddenly at his home near Melbourne on September 12, was the first professor of botany to be appointed in any Australasian university. Born at Liverpool on February 12, 1872, he was educated at Liverpool Institute and the University of Liverpool. He afterwards worked in the Universities of Leipzig (Ph.D.) and Oxford (D.Sc.). After a period as science master at the King Edward School, Bromsgrove, he became lecturer in botany at the Municipal Technical School and deputy professor in the University at Birmingham.

In 1906 the Government of Victoria decided that a successor must be appointed to Baron Sir Ferdinand von Mueller as Government botanist, and that the duties could be combined with those of a chair of botany at the University. For fifteen years, Ewart carried the heavy double burden, spending half his day at the University and half in the Herbarium at the Botanic Gardens, South Yarra, two or three miles away across the city. Ewart was further handicapped by lack of laboratories. Botany in the University had been split from the Department of Biology, and still shared the same building. It was not until 1929 that the Department was able to remove to buildings of its own. Ewart was justly proud of the fine Institute which was officially opened in November of that year. He had been elected a fellow of the Royal Society in 1922.

Ewart is best known to British botanists as a plant physiologist, the translator of Pfeffer's "Plant Physiology" and the author of a monograph on protoplasmic streaming published by the Oxford University Press. At about the time of his appointment to Melbourne he was engaged in work upon the ascent of water in trees (*Phil. Trans.*, 1905 and 1908), but after his arrival in Australia systematic and economic botany occupied most of his time. This did not prevent his publishing upon such a wide range of subjects as the longevity of seeds, photosynthesis, the chemistry of chlorophyll and the sensitivity of apples to poisons. This last work led him to hold certain views as to the cause of bitter pit in apples by metallic poisoning. His contributions to the flora of Australia number thirty-six papers. He also published a "Flora of the Northern Territory" in 1918 and in 1930 there appeared his "Flora of Victoria", a book of some 1,000 pages with 400 line drawings. This work is of great value to students in that State. Until its appearance, there was only an incomplete flora by von Mueller and the "Flora Australiensis" for reference.

Ewart's duties as a Government botanist compelled him to pay much attention to weeds and poisonous plants. His services were utilized by the Federal Government in connexion with stock poisoning along the overland route from the Northern Territory to Oodnadatta. In the winter of 1924 he visited Central Australia to examine the problem in the field.

Ewart was a man of robust physique. He delighted in country life and hard physical work. He found much pleasure in the labour of clearing and burning bush around his country cottage near Healsville, close to the heart of the giant eucalyptus forests. He was, however, keenly interested in forestry education and in efforts to develop a forest consciousness in Australia. In 1925 he published a "Handbook of Forest Trees" for use in Victoria, and at the time of his death he was chairman of the Forestry Examinations Board.

For the last two years of his life, Ewart had been far from well. He developed heart trouble. His sudden death, at the comparatively early age of sixty-five years, is a severe loss to his friends and colleagues.

T. G. B. O.

WE regret to record the death of Miss Lilias Armstrong (Mrs. S. Boyanus), which took place unexpectedly in London on December 9. Miss Armstrong was one of the foremost exponents of the science of phonetics, and was well known for her studies of the phonetic systems of the African languages. Lilias Armstrong, the daughter of the Rev. J. W. Armstrong, was a graduate of the University of Leeds. She joined the staff of the Department of Phonetics of University College, London, in 1918. Her abilities as research worker, teacher and organizer won her a world-wide reputation, which was recognized when at the close of the academic year 1936–37 the University of London conferred on her the title of reader. Miss Armstrong was the author of a large number of books dealing with the phonetics of English, French, Burmese, Somali and Kikuyu. It is especially in connexion with the two last named that Miss Armstrong's contributions to the study of languages were of especial note. Her phonetic studies put the grammar of these two languages on a new basis, her most remarkable discovery being the function in them of voice-pitch, by which in both, she discovered, grammar and meaning are determined.

News and Views

British Association: Sectional Presidents

THE annual meeting of the British Association will be held in Cambridge on August 17–24, 1938, under the presidency of the Right Hon. Lord Rayleigh. The following sectional presidents have been appointed: Section A (Mathematical and Physical Sciences), Dr. C. G. Darwin; B (Chemistry), Prof. C. S. Gibson; C (Geology), Prof. H. H. Swinnerton; D (Zoology), Dr. S. W. Kemp; E (Geography), Prof. T. Griffith Taylor; F (Economics), Mr. R. F. Harrod; G (Engineering), Prof. R. V. Southwell; H (Anthropology), Prof. V. Gordon Childe; J (Psychology), Dr. R. H. Thouless; K (Botany), Prof. W. Stiles; L (Education), Mr. John Sargent; M (Agriculture), Prof. R. G. Stapledon.

Mr. R. A. Smith

MR. REGINALD ALLENDER SMITH, who retires from the office of keeper of the Department of British and Medieval Antiquities of the British Museum (Bloomsbury) on January 4, has held that appointment since 1928. Mr. Smith had had a long period of previous service in the Department as assistant keeper, entering it when, under the late Mr. (afterwards Sir) Charles Hercules Read, it still included the exhibits in ethnography. Although the whole field of British prehistoric archæology lies within the range of Mr. Smith's expert knowledge, it is more particularly on the palæolithic period and the Iron Age that he is regarded as of the highest authority, and that on certain classes of disputed questions his judgment has been in a sense a court of final appeal. Of the official guides and other publications of the British Museum, of which Mr. Smith is sole or part author, the catalogue of the Sturge collection of stone implements is perhaps of the most enduring value to the student. Mr. Smith is not only the author of a large number of the archæological chapters in the various volumes of the "Victorian History of the Counties of England", but he has also made numerous valuable and authoritative contributions to the literature of archæology in the pages of learned and scientific publications dealing with the subject, more especially those published by the Society of Antiquaries of London, of which society he has acted as secretary and for some years past has been the director.

Mr. T. D. Kendrick

MR. THOMAS DOWNING KENDRICK, who will succeed Mr. R. A. Smith as keeper of the Department of British and Medieval Antiquities of the British Museum, has been an assistant keeper in that department for some years. Since the publication of his first book "The Axe Age", Mr. Kendrick has been recognized as an archæologist whose views are original, but at the same time carefully observant of the limitations of the evidence. Of recent years Mr. Kendrick has made a special study of the form and technique of the Celtic or British decorative art of the Iron Age and the British and Scandinavian art forms of the early historic period, on which he has contributed a number of papers to archæological publications. Among his more important published works are "The Archæology of the Channel Islands", of which one volume only has as yet appeared, "The Druids", "A History of the Vikings" and "Archæology of England and Wales, 1914–1931", the last-named in collaboration with Mr. C. F. C. Hawkes. He is also the editor of that valuable and scholarly series, "The County Archæologies".

Lord Nuffield's New Gift to Oxford

THE endowment of demonstratorships and assistantships in the Oxford Medical School, to be held by graduates from Australia, New Zealand and South Africa, will now be possible thanks to Lord Nuffield's latest gift to the School of £168,000. It is intended with this money to establish three demonstratorships in the pre-clinical departments of anatomy, biochemistry, pathology, pharmacology, and physiology, and three assistantships in the departments of medicine, surgery, obstetrics and gynæcology, anæsthetics, orthopædic surgery, and therapeutics. These posts will be held for a fixed period by graduates eligible for, or already holding, research posts in the universities of Australia, New Zealand and South Africa which grant medical degrees. The holders will be selected in rotation by these universities and appointed to the particular department in Oxford which is theirs. They will thus enjoy all the advantages of membership for a time of the Oxford Medical School. Oxford will benefit by the presence of these additional highly qualified workers; and the Dominions concerned will benefit by their experience on their return.

The Royal Botanic Garden, Calcutta

THE Royal Botanic Garden, Calcutta, is celebrating the completion of its 150th year on January 6, during the jubilee meeting of the Indian Science Congress, and a number of distinguished botanists from Great Britain expect to attend. The Garden was started at the suggestion of Lieut.-Colonel Robert Kyd, and continued as the Honourable East India Company's Botanic Garden until the Company relinquished its control of the government of India in 1857, when it became the Royal Botanic Garden, Calcutta. Colonel Kyd was appointed superintendent of the Garden and continued in that position until his death in 1793. Then it was decided to appoint a special officer, and the East India Company's botanist, Dr. William Roxburgh, held the post from 1793 until 1813. Roxburgh published his "Flora Indica", which became the basis of many subsequent Indian botanical works. In spite of a series of well-known superintendents (F. Buchanan (afterwards Hamilton), N. Wallich, W. Griffith, Hugh Falconer, T. Thomson, T. Anderson, C. B. Clarke, G. King), the Garden suffered vicissitudes of progress and serious set-backs. Cyclones practically devastated the grounds on more than one occasion, and once the Herbarium became seriously depleted through supplying other herbaria too lavishly. Recovery began under the administration of Dr. (afterwards Sir) George King, who retired in 1897; and still further improvements were made under Sir David Prain, who succeeded King and remained superintendent until 1905. Since that date, the Garden has continued performing important functions under the administration of several successive superintendents. The present superintendent is Mr. K. P. Biswas, who, until his recent promotion, was curator of the Garden Herbarium. For several months since relinquishing his curatorship, Mr. Biswas has been working at the Royal Botanic Gardens, Kew. The Garden lies on the right bank of the River Hooghly, at Sibpur, just outside Calcutta; and is now about 270 acres in extent. Apart from work of a 'pure' botanical nature, much work of economic importance —chiefly to India—is being pursued along lines similar to those obtaining at Kew. The authorities are to be congratulated on the Garden attaining its 150th anniversary, and Mr. Biswas on his recent appointment as superintendent.

An Early Text-book of Chemistry

THE small text-book on chemistry, "Tyrocinium Chymicum", of Jean Beguin, a native of Lorraine, was first published anonymously in 1610 and went through a large number of editions. The first issue was intended for the use of Beguin's own pupils in a school of pharmacy he established in Paris, but it was pirated and re-issued in Cologne in 1611. Beguin then re-issued it in 1612. Prof. T. S. Patterson, in a paper on "Jean Beguin and his *Tyrocinium Chymicum*", published in *Annals of Science* (2, 243–298; 1937), has given a very full account of the various editions of the book and a description of its contents. As he says, "it is certain, on account of the large number of editions issued, that Beguin's little book was found to be of great practical value, and it must have done much in unostentatious fashion to guide real chemistry along a sound experimental path. . . . Beguin was much under alchymical influence . . . but his was a common-sense alchymy and he used its philosophy in an entirely reasonable manner. There was little of the fantastic and nothing of the quack or impostor, or even of the willing dupe or self-deceiver, in him." In a preface by Barth in a later edition, it is said: "Beguin, on account of his virtue, opened his school in Paris—that celebrated emporium of all the wits, and compendium of the whole world—and did not burden his pupils and learners (for princes, counts, nobles, councillors and doctors, attracted by its novelty, meanwhile frequented his chemical laboratory) with useless and prolix comments and various descriptions of his remedies, but prepared in their sight candidly and simply, the secret medicaments of Quercetanus and others, of all kinds both solution and coagulation".

Science and Mankind

THE *Manufacturing Chemist* of November includes a further symposium of notes from contemporary scientific workers on "Science and Mankind". Contributions in the October number from Mr. H. G. Wells, Sir Richard Gregory, Prof. L. Hogben, Prof. H. Levy and Sir Daniel Hall are followed by others from Prof. J. B. S. Haldane, who stresses the importance of adequate organization to supply the Press with scientific news, and of thinking rationally about economics and politics, and Mr. C. S. Garland, who directs attention to the vital need for an organization which can speak for science as a whole and of the importance of having representatives in Parliament who are really concerned with the welfare of the profession as a whole. Sir Ernest Graham-Little outlines the contribution which medical science can make to improve social conditions. Dr. W. Cullen, while pointing out that the ultimate effects of a scientific or technical discovery are largely unpredictable, stresses the impossibility of stopping scientific and technical progress and, while condemning the prostitution of science as in warfare, directs attention to the way in which social conditions have been improved by scientific and technical advances. Prof. Alfred Stock expresses the hope that the progress of chemistry and physics has rendered war so terrible that the use of brute force will be renounced by the nations in reality, and that then science will be able to devote itself completely to the welfare, health and enjoyment of existence of mankind.

Research in Canada

THE nineteenth annual report of the National Research Council of the Dominion of Canada, for the year 1935–36, refers to the valuable work of the Division of Chemistry on the utilization of Alberta's natural gas. Optimum conditions have been determined for the production of ethylene, and a method has also been developed giving three to four gallons of benzene from each thousand cubic feet of Turner Valley stabilizer gas. Reference is also made to the synthesis of a number of plant-hormones and to the discovery that alkaloids of the giant larkspur, a plant growing wild in southern Alberta, are powerful insecticides. The Division of Chemistry has also developed an improved method of measuring the hiding power of paints, and the wax mixture previously developed for use in plucking chickens has now come into wide use in preparing poultry for the market. Dry-cleaning research has included the study of non-inflammable cleaning solvents, such as trichloroethylene, the manufacture of which is being undertaken in Canada. The Division of Biology and Agriculture has compiled an extensive review of the literature on weed killers as a guide to experimental work in this field. The extent of insecticide taint in wheat, the requirements of barley suitable for malting, especially for the British market, cold storage of fowls, fruit and other food products have all received attention, and physical conditions necessary for de-chilling boxed poultry have been established which prevent the formation of condensate, a blemish which lowers the market quality.

THE Division of Physics and Engineering has been responsible for a good deal of standardization work in co-operation with the National Bureau of Standards, Washington. A 'reverberation chamber' has been built and used for measurements of the sound-absorbing properties of various kinds, building materials for Government departments and commercial firms. Apparatus completed during the year has enabled the Division to make thermal insulation tests on large samples of insulating materials, partitions and wall sections. An experimental investigation of the heating of railway refrigerator cars in winter has been completed, and in addition to aerial surveys the Division has been concerned with a number of aviation problems, including the development of a new type of aircraft ski. The Division of Research Information is being vigorously developed and the report also refers to conferences on forestry and fish culture and to the work of a number of associate committees, as well as to the assisted researches, for which grants amounting to 158,968 dollars were provided during the year, and to the 685 scholarships awarded to 385 persons, representing total grants of 570,053 dollars.

Cancer Research in Australia

THE report of the eighth Australian Cancer Conference, which was held in Canberra in April last, shows that it was a meeting well attended by representatives from Australasia. The recommendations of the Conference of the previous year appear to have been largely acceptable to the Commonwealth Government for, on September 24, 1936, a National Health and Medical Research Council was instituted by an Order in Council. The recommendation that the Commonwealth Government should appoint an Australian Cancer Commission did not, however, prove acceptable. Among other resolutions of the present year's Conference may be mentioned a recommendation that the Commonwealth Government should make available the sum of £30,000 annually for the purpose of establishing a permanent and reliable system of medical research. There is little doubt that a most lively interest is being taken officially by Australia in the subject of cancer among its population. This is reflected not only in public action but also in the publications which appear from time to time dealing with various aspects of this subject. "Physical Aspects of Radium and Radon Therapy" is a booklet prepared by Dr. C. E. Eddy, physicist-in-charge of the Commonwealth X-ray and Radium Laboratory of the University of Melbourne, and Mr. T. H. Oddie, more especially for the use of radiotherapists and officers of local physical services. The booklet of sixty pages gives an extremely good account of the general physics of the substances and radiations used in radiotherapy together with an account of precautions necessary in using them. The relative advantages and disadvantages of radium and radon are also dealt with in a thoroughly explicit manner.

Edible Birds Nests in the Philippines

The edible nests of swiftlets, valued as a delicacy and as food for convalescents by the people of China, are built in limestone caves along the seashore in many parts of the Philippines. The export of the nests is in the hands of local Chinese merchants, and although accurate statistics are difficult to obtain it has been stated that the Netherlands Indies in 1927 exported 109,310 kilograms of nests valued at 822,913 guilders. In only one of the Philippine Islands, Bacuit, has an attempt been made to derive municipal revenue from the trade, when in 1927 the traditional ownership of the birds nest caves, which had existed for generations, was supplanted by municipal ownership and the annual leasing of the caves to the highest bidder. As a reply to this move, the Chinese dealers formed a ring so that the bidding, which reached 1,700 pesos in 1927, had fallen in 1936 to 500 pesos, and in a footnote to a recent paper on the subject, Canuto G. Manuel states that as no bid at all was offered in 1937, the caves have relapsed to the system of traditional ownership (*Philippine J. Sci.*, 62, 379, March 1937). From Bacuit, approximately 500 kilograms or about 100,000 nests are exported annually, but poaching of nests is common, and attempts to limit the collecting with the view of conserving the stock have met with little success. Nest collecting, however, is a dangerous occupation, and the fact that some inaccessible caves are tenanted by the birds, which belong to the racial form, *Collocalia francica germani*, provides for the survival of the swiftlet.

Literature of Food Investigation

IN its report for 1936, the Food Investigation Board stated that a committee had been appointed to review both the scope and the form of its publication, "The Index to the Literature of Food Investigation". The first number of this journal appeared in 1929 and at present it covers about a hundred scientific and technical periodicals, each number containing upwards of 2,000 references, in the form of elaborated titles that indicate the scope of the papers indexed, but omit all experimental data. The original intention was that the "Index" should deal solely with the transport and storage of foodstuffs; it now tends to cover, however, the wider diverse field that lies between agriculture, or production, and nutrition, or the use of food for the maintenance of health. The first number of volume 7, which covers the literature published in 1934, has been issued ("Index to the

Science and the Unobservable*

By Prof. Herbert Dingle, Imperial College of Science and Technology

A NEW phenomenon has appeared in modern physics, namely, an attempt to apply with rigour the principle that only that which is observable is significant. This is not intended to be a precise statement of the principle. It is at least vague, and perhaps inaccurate, but on that very account it is the most suitable statement with which to begin our discussion. For the principle itself has not yet been clearly isolated from its applications. Consequently it is manifested here in one form and there in another, appearing to some as an outstanding example of scientific arrogance and even absurdity, while to others it has an authority which raises it above common sense and reason alike. It is therefore important to try to understand the meaning of the principle and to reach a point of view from which its validity may be justly appraised.

It is Einstein who is responsible for the present virility of the principle. Let us hear him speaking of the crux of his theory—the idea of the simultaneity of events occurring at different places.

"The concept" of simultaneity, he says, "does not exist for the physicist until he has the possibility of discovering whether or not it is fulfilled in an actual case. . . . As long as this requirement is not satisfied, I allow myself to be deceived as a physicist (and of course the same applies if I am not a physicist), when I imagine that I am able to attach a meaning to the statement of simultaneity. (I would ask the reader not to proceed farther until he is fully convinced on this point.)"[1]

Here, on the other hand, is a comment by M. Jacques Maritain, the well-known French Catholic philosopher, on this passage:

"Let us, then, obey our author and read no farther, for this little parenthesis, 'the same applies if I am not a physicist', is of direct concern to us who have not the honour to be physicists, and it presumes to introduce us into the most fallacious metaphysics. . . . It is a fault so obvious to the eyes of a philosopher to confuse the *meaning* of a concept . . . with the *use* which may be made of the concept in this or that field of study, . . . that we hesitate to impute such a mistake to anyone, whoever he may be. Everything goes to show, however, that Einstein has made this mistake."[2]

R 271

It is not surprising that a physicist and a philosopher should take opposite views of this question, but the matter cannot be disposed of on simple psychological grounds. Here are the diametrically opposed views of two men of science:

"The general point of view" of relativity, writes Prof. C. G. Darwin, "of questioning the reality of anything unobservable is one of the greatest revolutions in scientific thought that has ever occurred. . . . The great idea which Einstein contributed to scientific philosophy was the principle that if a thing is essentially unobservable then it is not a real thing and our theories must not include it."[3]

This remark has caught the eye of Mr. Albert Eagle, now a mathematician, but in other days an experimental physicist, whose name is known wherever spectroscopy is practised.

"To me," says Mr. Eagle, "this 'great idea' is the most savage example of the application of what is known as the principle of *Occam's Razor* of which I have heard. . . . Einstein's 'great idea' requires us to surrender our common sense for the sake of an arbitrary dictum of his which he and his followers have raised to a fetish. It is preposterous, and to my way of thinking is so inherently idiotic that I cannot understand anyone wasting his breath in giving utterance to such a view."[4]

---

* From a Friday evening discourse delivered at the Royal Institution on November 26.

Finally, here is the attitude of another philosopher, Rudolf Carnap—perhaps the leading exponent of the most active of modern schools of philosophy, the so-called "logical positivism". Carnap, the philosopher, not only accepts the principle; he uses it to reduce to nonsense those branches of his own subject known as metaphysics and ethics.

> "I will call *metaphysical*", he writes, "all those propositions which claim to present knowledge about something which is over and above all experience. . . . Metaphysicians . . . are compelled to cut all connection between their propositions and experience; and precisely by this procedure they deprive them of any sense."[5]

Now when men who are neither fools nor liars agree that a certain idea is either the greatest discovery of a generation or the silliest nonsense imaginable, but cannot agree as to which it is, it is clear that there is more than a difference of opinion; there must be some defect of understanding also. It therefore becomes a matter of importance to state this principle precisely, so that we shall at least know what we are doing when we bless or curse it. And in seeking to assess its value we must avoid the error of ascribing greater or less weight to the opinion of a physicist than to that of another. Einstein is perfectly right in saying that if this principle holds for him as a physicist, it holds for him also if he is not a physicist; and M. Maritain offers him a licence which he cannot accept when he allows him to apply the principle in physics but not outside. If we talk nonsense, and plead in extenuation that we are only talking as physicists, we fall short of the ideal of rational speech, distinguished precedent notwithstanding. The question must be considered on general rational grounds. Are we to admit the unobservable into our scheme of things, or are we not?

Let me for a moment adopt the legal method, and state the case for each side independently, as an advocate might state it. Take first the case for the principle. It is necessary, say its supporters, as a safeguard against irresponsible invention. If we allow that an entity might exist and be significant to thought, although it is essentially unobservable, what is there to prevent us from postulating any number of such entities and invoking them to remove any difficulty that might arise? Suppose, for example, I assert that there is a binkum sitting on the table in front of me, and that this tremendous fact, rightly understood, is the final, completely satisfying solution of the problem of evil. If you reject the principle in question, you have no grounds for denying the statement. You may say that you cannot detect my binkum, but I reply that of course you cannot, because he is unobservable. If you want to know how his existence solves the problem of evil, I say that it is its nature to do so, and the definition of him, according to your own contention, is quite independent of any means you adopt to investigate him. If you ask, "What is a binkum, anyway?" I reply that that is immediately evident; I cannot put it into words, but everyone knows what a binkum is. If you retort that you do not know, I shrug my shoulders and say that you must be speaking as a physicist.

Stupid as this example sounds, it contains a precise parallel to the case of simultaneity. M. Maritain and those who agree with him claim that the simultaneity of spatially separated events is something independent of our means of observing it. When asked what it is, they claim that its nature is immediately evident and that everyone knows it. But Einstein says he does not know it, and Einstein is an honourable man. And the only reply is that Einstein and his followers must be speaking as physicists.

We can now press home the point. We agree, let me assume, that science and philosophy are better without the binkum: How, then, can we exclude him? Only, says counsel for the defence of the principle, by refusing to grant existence to anything that is essentially unobservable, and denying any unobservable property to an existent thing. That means that everything whose existence we acknowledge must be definable ultimately in terms of observation. If there is the slightest relaxation of this requirement, in comes the binkum with passport signed and sealed.

The case seems established, but we must hear counsel for the other side. His argument is a *reductio ad absurdum*. Certainly we do not want the binkum, he says, but your device for keeping him out is both presumptuous and absurd; you are throwing out the baby with the bath-water.

Consider for a moment what your principle implies. It asserts that there is nothing in the universe except what you can observe—nothing in the physical world beyond the reach of your senses. How do you know that the universe does not contain things apprehensible only by senses which you do not possess, which perhaps you have lost in the course of evolution or have not yet acquired ? Moreover, what about the past ? You cannot observe that, for it has gone ; therefore, you say, it has no meaning, it must not come into our description of reality. Such nonsense necessarily follows if your principle is granted. Exclude your binkum by all means—we hold no brief for him ; but find some sensible way of doing it, without assuming potential omniscience

The problem, I think, is now set clearly before us. If we admit the unobservable, there is no check on empty speculation ; if we reject the unobservable, we confine the universe within the bounds of human potentialities and make nonsense of history. What are we to do ?

It is evident that we must begin by examining the word 'unobservable'. Both sides wish to exclude the binkum ; both wish to allow the universe a richer content than we can at present perceive. The 'unobservable' that is to be proscribed must therefore include the obviously idle fancies but exclude the legitimately transcendental.

There are reasons of various kinds why we may be prevented from observing a thing; but I think they can all be summarized under four headings. First of all, there is what I will call the *practically* unobservable ; namely, that which is unobservable because of the practical difficulties of observing it. The far side of the moon affords an example. That region is unobservable because we have not solved the problem of interplanetary travel, or performed some equivalent feat of practical ingenuity. It is conceivable that in time this disability will be removed, so that practical unobservability may be merely a temporary characteristic.

Secondly, there is the *humanly* unobservable ; by which I mean the unobservable which is so because we do not possess the necessary faculties for observing it. I cannot, of course, by the nature of the case, give examples of this, but I can give analogies. A great deal of the universe would be humanly unobservable if we had no sense of sight ; and to the musically insensitive the significance of a great composer may be said to be humanly unobservable. If, then, there is in the universe some existence which no creature has the faculty of apprehending, that existence is humanly unobservable.

Thirdly, there is what I will call the *physically* unobservable. A thing may be said to be physically unobservable when we have the faculty for observing it if Nature will co-operate, but Nature gives that faculty no opportunity for exercise. Thus, if somewhere in space there occurred an event from which no signal—light ray or sound wave or anything else—proceeded to other places, and if there were repulsive forces which prevented us from ever reaching the place of occurrence, that event would be physically unobservable.

Lastly, there is the *logically* unobservable ; namely, those things which we cannot claim to have observed without breaking the laws of reason. I doubt if this class is actual, since logic and observation are essentially independent, but it must be included because a great deal has been written about it. An example might be the observation of an object both larger and smaller than a given object ; but I give this example with some hesitation because geometers have an uncanny knack of inventing spaces in which such relations might not be incompatible. Be that as it may, however, if we grant a certain minimum of common agreement—such as the acceptance of Euclidean geometry in the present instance—logical unobservability becomes an intelligible notion, and we will accept it as a candidate for inclusion in our principle.

Now this classification may be simplified ; for, whatever may be the ultimate truth of the matter, it is not necessary for our purpose to put the humanly and the physically unobservable in separate classes. I will therefore group them together and call them jointly the physically unobservable. The justification for this is that we cannot tell, in any given case, with which class we are dealing. If, for example, a certain substance appears tasteless to everyone (that is, its taste is unobservable), it is impossible to say whether that is because it has a taste which our senses are not keen enough to detect, or because it has no taste to be detected. But now our principle is essentially one which, if valid, must be used ; it is not a creed which we are merely called upon to state and may then ignore. The humanly and the physically unobservable, then, become one class so far as our problem is concerned, for if in practice we reject one, we automatically reject the other also.

We have, then, three classes of unobservables, and I think the distinction between them may be expressed most simply in the following way. Let us suppose that we have discovered all the means of observation that exist in the universe, and know all their properties completely. We might then be able to imagine other means of observation which do not exist. Anything which would be observable by such imaginary means, but not by the existing means, would be *physically* unobservable. Anything which would be unobservable by *any* means, existing or imaginable, would be *logically* unobservable. Anything which would be observable by the existing means if we were also omnipotent, but which actually is unobservable because we cannot make full use of the means of observation which exist, would be *practically* unobservable.

We can now proceed a stage further. We have just seen that, for our purpose, the humanly and the physically unobservable become one class because we cannot at present distinguish between them. Let us look, then, at our latest classification, to make sure that the three types of unobservability we have now reached are immediately distinguishable. It is fairly evident, I think, that they are, if we grant the initial supposition that we have discovered all existing means of observation. For brevity, I will call that the assumption of *omniscience*, and you will understand that by this word I do not mean knowledge of everything that exists or that can be observed, but complete knowledge of the existence and properties of every means by which observation is possible. For example, omniscience implies complete knowledge of all the properties of light, but not necessarily of all objects which are visible. Now, clearly, this assumption of omniscience is open to challenge, and it is therefore necessary to see how our classification looks if it is removed. Can we then still recognize the three classes as distinct ?

There is no difficulty, I think, with the logically unobservable. Since this class consists of things which are not even *imaginably* observable, it makes no difference how much we know of *possible* observability. There can be no possible means of observation that is not imaginable. The logically unobservable, then, forms a definitely distinguishable class, independently of our assumption of omniscience.

The case is different, however, with the practically and the physically unobservable, for these classes *cannot* be distinguished if we do not regard ourselves as omniscient. We said that the far side of the moon was practically unobservable, but if we are not omniscient, how do we know that when we have overcome what seem to be the present obstacles, Nature will not face us with some unexpected difficulty like that which she kept in store for our efforts to determine our motion through the ether ? If she does, and persists in doing the same kind of thing, we shall have to call the far side of the moon physically and not only practically unobservable. And, on the other hand, when we say that absolute motion is physically unobservable, we are again assuming omniscience. We cannot observe such motion by optical, acoustical, electro-magnetic or any other means within our present knowledge, but, without the assumption, who can say that there is not some undiscovered physical medium through which it may be detected ? If there is, absolute motion is merely practically, and not physically, unobservable. It is clear, I think, that unless we are omniscient the two classes are indistinguishable.

Our analysis of unobservability, then, finally brings us to this. If we assume that we are omniscient we can distinguish three classes—the *practically*, the *physically* and the *logically* unobservable. If we do not assume that we are omniscient we can distinguish only two classes—the *actually* and the *logically* unobservable, let us call them. The importance of this conclusion for our purpose is this. We are going to look at the actual practice of physics, to see what kinds of unobservable are excluded and what kinds are not. If we find that a distinction is made between the practically and the physically unobservable, then we know that physics is assuming omniscience; but if no distinction is made, then there is no such assumption.

Let me state the result at once, afterwards giving examples to justify the statement before proceeding to consider the validity of the principle we are considering in its definite form. The practice of physics is to recognize three classes—the practically, the physically and the logically unobservable. Of these it excludes the physically and the logically unobservable from its considerations, and aims at describing the universe in terms of the observable and the merely practically unobservable only. It thus assumes omniscience, in the sense in which I have defined the word.

It will not take us long to see that physics includes the practically unobservable. No physicist denies that the moon has a far side in the same sense as it has a near side. We assume without question that the earth has an interior, that there are stars outside the range of our telescopes, and regions beyond the obscuring clouds of the Milky Way. All these things could be observed if known means of observation have precisely the properties we believe them to have and we had the skill to make full use of them. Hence the practically unobservable is admitted to physical theory.

We may deal equally summarily with the logically unobservable. Nasty things have been said about the reasoning of some modern physicists when they step outside the bounds of their equations, but I do not think the bare, unadorned physical theories themselves have been called illogical, either with pride or with shame. If, then, the structure of physical theory allows ontological significance to anything which is logically unobservable, it does so through an oversight, and theory will undoubtedly be reformed as soon as the oversight is discovered. We may say, therefore, that the practice of physics is to reject the logically unobservable.

But now, the unobservables the rejection of which has caused all the controversy belong to neither of these classes. Let us fix our attention on the example of absolute simultaneity, with which the discussion began. This, as we know, is rejected, and that cannot be because it is practically unobservable, for physics reeks of the practically unobservable. Nor is absolute simultaneity logically unobservable. We can conceive that the universe might be such that two events at different places might occur at the same time in an absolute sense, and that this fact might be observable. We cannot, then, escape from the conclusion that absolute simultaneity belongs to a third class of unobservables, which we shall see is what I have called the class of physically unobservables; and the recognition of this class commits physics to the assumption of omniscience.

To see that absolute simultaneity is physically unobservable, let us look at the obstacle that prevents us from observing it. Why can we not say, in an absolute sense, that two events occurring at different places are simultaneous? It comes down to the fact that we can know of the events only through some agency which travels from them to us and takes time to do so. We know of most events when we see them, but we do not see them at the moments at which they occur because the light which makes them visible takes time to travel. We can, of course, allow for this by calculating how long the light has taken to travel, but when we do so, according to standard methods and principles, we find that the results depend on the way in which we happen to be moving with respect to the bodies on which the events occurred. Furthermore, we cannot distinguish in an absolute sense between one state of motion and another. Hence we do not know what allowance to make for the time of travel of the light, and therefore cannot determine absolutely whether the events were simultaneous or not.

The unobservability of absolute simultaneity, then, depends on the fact that we cannot determine unambiguously how long light takes to inform us of an event; or, more generally, how long after an event it is possible for us to know of it. This ignorance, of course, would not be necessary if we could know of an event immediately it occurred—if, this is to say, we could observe it by some messenger which travelled at an infinite speed. This is not pure fancy. Before the time of Römer, in the seventeenth century, it was believed that light might travel at an infinite speed; and before the theory of relativity arose, it was believed that gravitational action was transmitted instantaneously. It is not uncommon, too, to imagine that there might be instantaneous telepathic communication. We can at least, then, *conceive* that an instantaneous messenger might exist, and therefore absolute simultaneity is not *logically* unobservable. It is unobservable simply and solely because, so far as our present survey of the universe has gone, there is no evidence that it is possible to learn of a distant event at the moment at which it occurs. In other words, absolute simultaneity is *physically* unobservable.

We can now, at last, give a rigorous form to the principle which is the subject of our inquiry. It is this: that *only that which is practically observable*—that is, only that which would be observable if we were able to use known means of observation to the known limits of their possibilities—*is significant.*

The next step, clearly, is to examine the credentials of this principle on general rational grounds, but before doing so I want to give another example of its application, in order to emphasize the fact that it is not an unimportant appendage of physical theory, but the very mainspring of the most prominent modern developments. Heisenberg's uncertainty principle is perhaps the best-known example, but I will not deal with that because it is too closely bound up with other factors which there is no time to consider. I choose instead a subject which stresses the point still more forcibly because it is not generally regarded as exemplifying the principle in question, but is attacked or defended on quite other grounds. The principle has taken root so deep in the minds of physicists that they employ it unconsciously, and justify their action by arguments which appear to others either incomprehensible or absurd. I am speaking of the idea that the physical universe is finite but boundless. This idea can be made intelligible in five minutes when presented as an example of the principle of rejection of the physically unobservable, and I believe that those who accept it are convinced of its rationality because they have already accepted that principle. They are not aware of this source of their conviction, however, and therefore have to justify their belief by saying that space is "curved", that it "bends back on itself"—an "idea" which I do not think it is humanly possible to grasp except as a metaphor of the kind one meets with in the "metaphysical" poetry of the seventeenth century. Whether or not that psychological diagnosis is accurate, however, is unimportant; the main point is to see that, in terms of our principle, the idea that space is finite and boundless is intelligible without calling on such unimaginable notions as curvature.

The idea is that if we were free to move about in space eternally, wherever Nature led, we would always find ourselves apparently in the midst of a collection of stars or nebulæ, though we could not for ever be meeting new objects, but would have to endure the tedium of seeing the old familiar faces endlessly, without relief. Like our former example, this idea, in its modern form, originated with Einstein; let us see how it has impressed his contemporaries. Sir Arthur Eddington, who thinks very highly of it, writes thus:

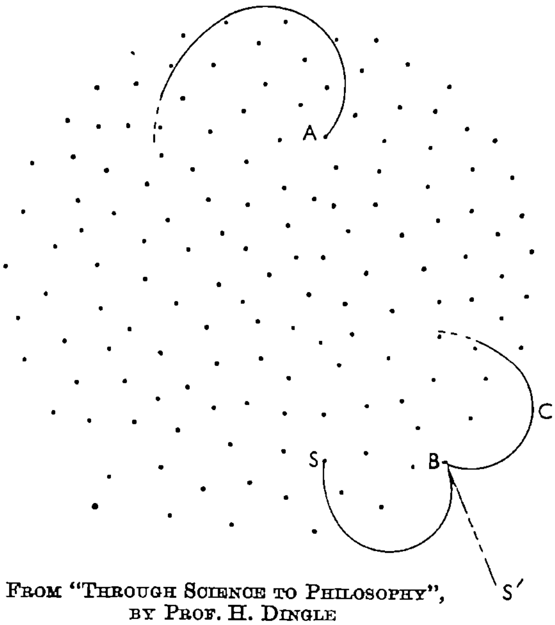
> "Einstein made a slight amendment to his law to meet certain difficulties that he encountered in his theory. There was just one place where the theory did not seem to work properly, and that was—infinity. I think Einstein showed his greatness in the simple and drastic way in which he disposed of difficulties at infinity. He abolished infinity. He slightly altered his equations so as to make space at great distances bend round until it closed up."[6]

On the other hand, here is the stimulating Mr. Eagle again:

> "In pre-Einsteinian days if people had been told that an author's theme in his book had been that external reality only possessed three spatial dimensions, and that therefore to talk of 'curved three dimensional space' was pure nonsense, they would have replied that they thought only lunatics thought otherwise. Now this conception is widely regarded in many circles as a 'probably may be true' one. This to me seems the measure to which both the scientific world and the general public have been bluffed by the theory. Future scientific historians will probably regard the theory as a befitting product of a mad age in the world's history."[7]

Prof. E. A. Milne is scarcely less contemptuous of this manifestation of Einstein's greatness.

> "It is not necessary", he says, "to employ the vague, ill-understood, probably meaningless concept of closed, finite expanding space."[8]



FROM "THROUGH SCIENCE TO PHILOSOPHY", BY PROF. H. DINGLE

Well, the symptoms are familiar. Again we have the alternative estimates of supreme greatness and supreme folly, and we might suspect that the same misunderstanding is at the bottom of the trouble—as, in fact, it is. Let us begin with a finite collection of stars (or nebulæ) in a space which we suppose extends to infinity in all directions; we are somewhere in the midst of the collection—say, at *A* (see accompanying figure). Now suppose we try to get outside into the empty spaces. We cannot, because the gravitation of the system keeps all material bodies inside; the faster we move the greater is the attraction and we find ourselves following some such path as that shown in the diagram. It is the same with light; that also is drawn back, and cannot illuminate whatever external objects there may be. In fact, no physical existence that we know of can escape. All that is perfectly conceivable.

We picture, then, a finite universe from which we cannot escape. The next point is that it is impossible for us to know whether we are at its centre or its boundary; in either case we appear to be surrounded by stars on all sides. Obviously an observer at the centre (or at A) sees stars all round, but so does an observer at B, for the light of the stars inside is bent, so that he sees them whichever way he looks. The light of a star at S, for example, is bent so that the star appears to be at S'. This is a very ordinary phenomenon, exemplified every time we look at a mirror; an object appears in the direction of the light that enters our eye, and not necessarily where it actually is. We are therefore not only confined within the universe, but also necessarily without the possibility of the *experience* of being at the boundary; however we move, and wherever we go, we must always see the same kind of thing—stars more or less uniformly distributed all round.

All that is of the nature of simple, traditional physics: now comes the crucial point. Since the region outside the system is physically inaccessible and unobservable, and the *experience* of being at its frontier is physically unattainable so that it is never possible for us to know whether we are there or not, we leave these things outside our description of the universe. We give the name 'space' to the volume which contains what we can observe, and describe it simply according to our experience as both finite and boundless. We can still, of course, conceive that there is an infinite region outside (wherever 'outside' may be), but that is merely another way of saying that the region is not *logically* unobservable. The rejection of infinite space is, in fact, precisely similar to the rejection of absolute simultaneity: it represents an economy of ideas—we are to introduce no conceptions which are not necessary for the description of the physically observable.

It may be worth while to point out that this account of finite boundlessness differs from the statement that space is curved in the fact that it says nothing about any intrinsic *property* of space. There is no need to try to think of emptiness with a curvature; we have simply to think of possible experience, and keep within its bounds. Of course, for mathematical purposes the conception of curvature is useful because it allows us to employ the technique of Riemannian geometry to solve particular problems, and for the mathematician it may have some æsthetic value, as the poetry of Mr. T. S. Eliot is said to have for those "in the know". But for the purpose of understanding it is worse than superfluous; it is definitely misleading.

What, now, of the validity of this principle, which has taken charge of physics and threatens to direct all future philosophical thought? Let me repeat the principle: it says that *nothing which is logically or physically unobservable is significant.* This statement must be appraised on pre-scientific, general rational grounds, and we can best approach the task by returning to the rival arguments set out earlier and considering them in the light of our rigorous statement.

The essence of the argument for the principle is that it is needed to prevent arbitrary invention of existences or arbitrary dogmas about them; and it meets this requirement by saying, in effect, that everything that exists is observable by known means. The argument against the principle is that we have no right to assume omniscience; that although it may be granted that the logically unobservable cannot exist, it is presumptuous to say the same of the physically unobservable.

We are therefore in this dilemma. If we deny the principle, we have no check on idle invention; it may be that all that we know, and have taken such pains to find out, is trivial, while the great, important facts of the universe are not even suspected and are unattainable. On the other hand, if we accept the principle, we close the door to all experience outside that which our present knowledge allows. Let me repeat that this dilemma is not a domestic affair for physicists. In physics it concerns at present only existences observable by sense perception, but clearly it is equally relevant, in the appropriate forms, to all spheres of thought in which we regard ourselves as apprehending some independent existence by means of human faculties.

This last sentence, I think, gives the clue to the solution of the problem: "all spheres of thought in which we regard ourselves as apprehending some independent existence by means of human faculties". That is the attitude which I have assumed throughout this discussion—the attitude of naïve realism in which we picture an objective universe existing independently of our thought of it and our examination of it. It is the attitude which we always assume in everyday intercourse and in most scientific discussions also. We regard scientific research as an exploration of this independent universe, an attempt to discover what it contains and to understand the pre-established relation of one part with another. It is this conception of science or philosophy that makes possible the dilemma by which we are faced. If the universe exists independently of our experience of it, then clearly it is presumption on our part to deny that it can contain anything inaccessible to experience. On the other hand, if we abstain from this presumption we make all inquiry a mockery, for we have no guarantee that anything that we may discover is more than a triviality, an insignificant part of a universe the essential elements of which are eternally unknowable.

But suppose we take the idealistic view, regarding our experience, our observations, as the primary data, and the universe as a mental construct formed to give rational coherence to those observations. The whole matter then appears in a different light, in which the dilemma is no longer seen. The statement that nothing which is logically or physically unobservable is significant is simply a statement of our aim as scientists or philosophers; it means that we confine ourselves to our purpose of deducing a universe from our observations and do not allow our fancies to intervene. There is no assumption of omniscience because there is no independent universe to know, and the arrogance disappears because we make no claim to know all the possibilities of observation. We set no limit to the possibilities of experience; we simply refuse to assert anything for which we have no (direct or indirect) justification in experience, and as observation grows the universe grows also. The objection to the principle therefore vanishes completely, from the idealistic point of view.

On the other hand, the objection to denying the principle by no means vanishes. If we do not exclude the physically unobservable from our description of the universe, we still have no grounds for not admitting the binkum and so reducing philosophy to a farce. When M. Maritain claims that a thing is independent of our observation of it, he immediately makes it impossible for us to know that we are saying anything of the least importance about it, no matter whether we adopt the realistic or the idealistic point of view. If we are realists the thing may be essentially beyond apprehension; and if we are idealists we may form it equally legitimately from observation or from fancy.

The position, then, is this. If we take the realistic view, we are left with an unresolved dilemma, but if we take the idealistic view, the principle becomes simply a statement of the object at which science has aimed throughout its history. It is not my purpose to comment on the age-old problem of idealism *versus* realism; I am concerned only with the attitude implied in modern scientific developments, and the point I want to emphasize as clearly and unmistakably as possible is that anyone who regards the recent trend of physics in general, and the theory of relativity in particular, as legitimate science or philosophy or intellectual activity bearing whatever name may be thought honourable, must either be an idealist or presume that he is omniscient I do not wish in this place to plead the cause of either of the alternatives open to the humble. I am not anxious to cry, "Vote for realism, and down with relativity!" or "Support idealism and relativity, and throw realism to the dogs!". That is a matter for personal predilection, but it is a matter for pure reason to show that those are the only alternatives open to anyone who is not prepared to assume that he is omniscient.

The striking divergence of opinion with which we opened can now, I think, be understood. Those who, like M. Maritain and Mr. Eagle, see the principle in question as an example of presumption arising from ignorance, are realists—by which I mean that they instinctively think as realists, whether or not they would accept the title. On the other hand, those physicists and philosophers who accept the principle are, by the same criterion, idealists, though most of them speak our ordinary, everyday language which has accommodated itself to the realistic outlook. In terms of that language their utterances necessarily appear arrogant; what they apprehend instinctively as the wisdom of a self-imposed discipline is clothed in sentences which suggest to the realist the idea of arbitrary dogma. The divergence, arising as a difference of philosophical attitude, is accentuated by the necessity of expressing idealistic principles in realistic terms.

Printed in Great Britain by
FISHER, KNIGHT, & CO., LTD., The Gainsborough Press, St. Albans

Literature of Food Investigation" : 7, No. 1, March 1935. Compiled by Agnes Elisabeth Glennis, assisted by Gwen Davies. Pp. 371+xiii. (London: H.M. Stationery Office, 1937.) 5s. net); but it is hoped during the next twelve months to bring the "Index" up to date and to complete abstracts of the literature published in 1935 and 1936, which will form No. 2 of vol. 7, and vol. 8. Meanwhile the first number of vol. 9, containing abstracts of papers published during 1937, is in preparation. The papers noted in the present number are arranged in fifteen sections, and there is an author index extending to twenty pages. The compiler gives a brief review of developments during 1933–34, selecting the following subjects: gas-storage of meat and fruit, storage of rice, eggs, anti-oxidants for fats and oils, and engineering. Attention is directed to the fact that 1934 was the centenary of the invention of the earliest continuous refrigerating machine, by Jacob Perkin, which used ether as refrigerant, and was the first real landmark in the history of modern refrigeration, so far as technique is concerned.

Studies in Ancient Astronomy

A SMALL collection of papers recently published in *Meddelande Från Lunds Astronomiska Observatorium* makes an interesting contribution to the study of the early history of astronomy. In an article entitled "Greek Cosmogony and Astronomy", Dr. K. Lundmark briefly traces the development of Greek astronomy from the first indications of some primitive astronomical knowledge found in the Homeric poems and in the work of Hesiod to the great work of the Alexandrine astronomers and mathematicians, culminating in the production of the "Almagest" in the second century A.D. A very useful synopsis for rapid reference is included of Greek astronomers and their contributions to astronomical ideas and observation. In another paper, P. Collinder studies the distribution of the birthplaces of the astronomers of antiquity. He remarks that the Hellenic peninsula itself produced but few in contrast with the west coast of Asia Minor, with Alexandria and the coast of southern Italy. It was, in fact, in the great merchant and shipping towns of these latter localities where the Greeks would best receive the importation of astronomical knowledge from the Babylonians, Egyptians and Phœnicians. A further contribution by B. Svenonius describes his examination of certain rock sculptures found in Ostrogothie, Sweden. These engravings, which may date from the bronze age, include amongst the representations of men, animals, ships and primitive weapons, groupings of small cavities, which it is agreed represent groupings of the bright stars into constellations. M. Svenonius identifies the following constellations: the Great Bear, Cassiopeia, Perseus, Cepheus, Auriga, Orion and Leo. An examination by earlier Swedish investigators of similar rocks found in Bohuslän leads to the same general conclusion that the forms of several easily recognizable constellations were copied by some of the prehistoric watchers of the skies. In a supplementary note, A. Ohlmarks contributes remarks on these rock engravings and their relation to the history of early religious beliefs.

Physics Research at Osaka

THE volume of *Collected Papers* for 1936 from the physics section of the Faculty of Science of Osaka University includes 33 papers which have appeared in scientific periodicals between February 1936 and March 1937. The papers are in their covers as issued as reprints and are bound together with wire to constitute the volume, which is 10·1 in. × 7·4 in. × 1 in. Twenty-two of them are from the *Proceedings* of the Physico-Mathematical Society of Japan, five are Reports of Radio Research in Japan and two are from the Institute of Physical and Chemical Research, and five other institutions contribute a paper each. The papers from the Physico-Mathematical Society are nearly equally divided between problems of atomic structure and radiation, hydrodynamics and electricity. A table of contents is provided in which each paper is numbered and the number is printed on the right hand top corner of the cover of each so that reference is easy. The various publications from which the papers are reproduced appear to have very nearly the same size of page, slightly larger than that of the volume, except in one instance in which the page is 0·2 inch less wide. This inexpensive form of issuing collected papers seems to be on the increase.

Films for Promoting International Understanding

IN *Film Progress* of July, the Central Information Bureau for Educational Films, Ltd., announced the impending release of "Living in Wales", the second of its series of talking films designed to help the peoples of the world to gain a clearer insight into each other's lives and thereby to promote sympathetic mutual understanding. The first of the series, "Living in the Netherlands", is reported to have been well received both at The Hague and in London. "Living in Wales" was used at the Congrès Internationale de l'Enseignement Primaire et de l'Education Populaire to illustrate an address by Dr. G. H. Green of Aberystwyth on "The Cinematograph as a Means of Education for International Understanding". The paper emphasizes the fact that the educational film is not merely an additional means of illustrating or confirming what the teacher conveys through the medium of words, but also provides the closest possible approximation to real first-hand experience. It postulates four essentials for the success of films as instruments for promoting international understanding: an adequate supply of suitable trustworthy films, efficient machinery for production, distribution and publicity, comprehensive experiments and investigations into the technique of education by means of the film, and a centre for acquainting teachers not merely with the films and projectors available but also with all matters relating to films. The same issue of *Film Progress* announces the decision of Osaka City authorities to build an "Educational Movie Hall" at a cost of 500,000 yen for the benefit of primary school pupils.

Economic Aspects of the Cotton Trade

"WORLD COTTON PRODUCTION AND TRADE" is the first of a series of studies of the principal agricultural products on the world market to be published by the International Institute of Agriculture, Rome (price 30 lire). This comprehensive monograph, consisting of 480 pages and 20 maps and diagrams, is divided into four main sections. The first deals with the geography of cotton production, describing the agricultural conditions of the humid and sub-humid zones of the rain-grown crop, and the arid or semi-arid zone of irrigated cotton. Part 2 describes the conditions of cotton marketing and movements of cotton prices, while Part 3 is concerned with the evolution of world cotton trade. The fourth part deals with the national and international aspects of the industry, separate sections being devoted to the principal countries concerned. It is evident that the economic problems of the cotton trade are closely linked up with the wider financial and commercial problems of the world. The relatively large expansion of the smaller cotton countries during an economic crisis simultaneously with the general contraction of the world cotton industry, presents one of the most significant aspects of the world economic problem. The position was aggravated by the policy of the United States of maintaining cotton prices at an artificially high level and closing their market to European goods. It is considered that from the point of view of a rational world economic system, the various branches of agriculture should be developed in those parts of the world which are most suitable. Under such a system the United States would regain its position on the world cotton market, which is regarded as its full right, but the conditions of such a recovery would be the abandonment in all countries of the prevailing tendency towards economic isolation and a development of a greater degree of international co-operation.

Progress in the Meteorological Office

THE eighty-second year of the Meteorological Office is referred to in the annual report of the Director for the year ended March 31, 1937, as one of planning and preparation with the object of providing the greatly extended meteorological services required by the expanding Royal Air Force and by the increase of flying on civil air routes. These projected increases of meteorological activity have made it necessary for new staff to be recruited and trained in the special work required of them; in particular, the need for trained forecasters has had to be met in order to staff the principal forecasting centres on the various flying routes. The new Empire Air Mail Scheme led to the formation of a new division of the Meteorological Office in 1935 to organize the meteorological services of the trans-Atlantic and Empire air routes, the duty of advising the Governments of territories traversed by the routes having devolved on the Meteorological Office, and throughout the year under review that division was preparing for the new mail service. The forecast and aviation division has given particular attention to the information required by civil and R.A.F. aircraft in connexion with flying in and through clouds—information about the winds to be expected and warnings of dangerous conditions likely to lead to ice accretion between certain heights in strata where temperature lies between 0° F. and 35° F. and other circumstances are favourable for such accretion. It has now been determined that really dangerous conditions are scarcely ever found when temperature is more than a few degrees above or below the freezing point.

Motor Traffic and Wild Life

IN a discursive and interesting paper read before the Zoological Society of London (*Proc. Zoo. Soc.*, Ser. A, 173; 1937), Surgeon Rear-Admiral Beadnell has given an indication of the destruction of wild creatures caused by motor traffic in Great Britain. In the years 1932–36, in travelling by motor-car and pedal-cycle on roads in England, Wales and Scotland, he counted 2327 dead animals in 10,000 miles, or 23 in every hundred miles. The kill was made up in the following proportions: birds 81 per cent (1885 individuals), rabbits 14 per cent, hedgehogs 4 per cent, rats 0·5 per cent, and the remainder was made up of frogs, toads, moles, snakes, dogs, cats, two sheep and one forest pony. It may be taken that the number counted during a rapid survey falls far short of the total number slain, and indeed were it not that many motorists when driving are highly regardful of wild creatures, the number would be much greater than it is. But the count does not suggest that motor traffic will make appreciable inroads upon the stock of wild animals, for the numbers are insignificant compared with the rate of increase of the common species which usually fall victims. An odd death which came to the notice of the writer was that of a dog fox in beautiful pelage, which during a snowstorm in the north-east of Scotland leapt over a stone wall against the wings of a heavy lorry.

Policy in Pig-Feeding

THE pig and bacon industry in Great Britain is dependent upon imported and home-grown cereals, and during the last twelve months feeding costs have risen by 30 per cent without a compensating rise in the price of bacon. The Bacon Development Board has accordingly completed an inquiry into the possibility of replacing cereals by other foodstuffs, and the report of A. N. Duckham has been published as Bulletin No. 2, "Substitutes for Cereals in Pig-Keeping" (Bacon Development Board, 1937. Price 2*s*.). The general conclusion is that if some sacrifice of growth rates and carcass quality is allowed and adequate facilities for growing and storing substitutes are made available, then cereals may be replaced in part by potatoes, sugar-beet and other home-grown root and fodder crops or by-products either in fresh or processed forms. At present, the use of these cereal substitutes may not be economical in Great Britain, but conditions may arise when cereals, home produced or imported, may be in short supply or at greater cost, and under such conditions it is believed that pig production could be kept up as an economic proposition, making an appreciable contribution to the national supply of meat and animal fat for human consumption.

Water-Power of the World

THE United States Geological Survey has attempted a new estimate of the potential and developed water-power resources of the world. The estimate is based on ordinary medium flow and 100 per cent efficiency. Potential power is based on existing flow and disregards storage except in the case of constructed reservoirs. The estimates for developed power are based on installed capacity of machinery at constructed plants, which averages two or three times the potential power at low flow at the same sites. Thus, for example, the potential power at utilized sites in France amounts to 21 per cent of the total potential power of that country, but in effect amounts to 44 per cent of the theoretical total power resources. With this proviso, it is noted that about ten per cent of the potential water-power of the world is developed. The capacity of the constructed plant in the world at the end of 1936 was 60 million horse-power, or an increase of 160 per cent in sixteen years. The United States show by far the greatest development, but Canada, France, Italy and Japan have high figures, and Norway, Germany, Sweden, Switzerland and the Soviet Union show rising totals.

Biochemistry in India

THE Society of Biological Chemists, India, publishes a useful review each year of the results of investigations in biochemical subjects which have been carried out in India during the previous twelve months. The current number (*Annual Review of Biochemical and Allied Research in India*, 7, 1936. Pp. 165. (Bangalore: Society of Biological Chemists, India, 1937.) 3*s*.) is divided into seventeen sections, of which about two-thirds are devoted to various aspects of agricultural science. Sections are also given to vitamins and hormones, pharmacology and human physiology, pathology and bacteriology. The papers reviewed have, of course, been published in full in other journals, chiefly Indian, but this volume provides a useful summary of work which is not always easily accessible. It is noticeable that the size of the volume has been increased considerably since this review was first published, a tribute to the steady progress research is making in India.

Diseases of Fur Animals

THE United States Department of Agriculture, Washington, D.C., in Farmer's Bulletin No. 1777, gives an account of the diseases attacking fur-animals on the farm, together with methods of control. Descriptions are given of distemper, paratyphoid infection and encephalitis of foxes, of hookworm, tapeworm and fluke affections, and of external parasites such as fleas, lice and sarcoptic mange, as well as of nutritional disturbances. Useful information is also given on farm sites and structure, their sanitation and disinfection. The Bulletin should be of value to those engaged in the fur industry in Great Britain.

Fire at Messrs. Flatters and Garnett, Ltd.

A SERIOUS fire occurred on Sunday morning, December 19, at the laboratories of Messrs. Flatters and Garnett, Ltd., the well-known Manchester firm of microscopists. The chemical and microscopical laboratories were completely burnt out, but a considerable number of mounted slides were saved. The photographic and lantern slide department was only slightly involved and the new instrument workshop, for manufacturing microscopes, micro-projectors, etc., escaped entirely. All the staff is being retained, and work has already been resumed in temporary laboratories. Stocks of most of the firm's chemical specialities are held at the head office, 309 Oxford Road, Manchester, 13, which is two miles from the laboratories.

Awards of the Institution of Naval Architects

THE Council of the Institution of Naval Architects has awarded the premium of the Institution for the year 1937 to Mr. R. W. L. Gawn, for his paper "Results of Experiments on Model Screw Propellers with Wide Blades", the Wakeham Prize (1937) to Mr. H. Lackenby, for his paper "Re-analysis of William Froude's Experiments on Surface Friction and their Extension in the Light of Recent Developments", and the Duke of Northumberland Prize (1937) (awarded by the Council of the Institution in connexion with the award of National Certificates in Naval Architecture) to Mr. D. N. Wallace, of the Royal Technical College, Glasgow.

International Federation of Eugenic Organizations

THE report of the Twelfth Conference of the International Federation of Eugenic Organizations, held at Scheveningen, Holland, in July 1936, has just been issued, and can be obtained from W. P. van Stockum and Zn., N.V., The Hague, Holland, price three Dutch florins. A list of the fifty delegates from twenty countries is followed by twenty-five papers presented at the meetings. The papers range from the classification and inheritance of mental defects to mutations in plants and man, twin studies and the problems of sterilization in Germany, Denmark, Sweden and the United States. The 119 pages end with a report of the Human Heredity Bureau and also reports on the standardization of measurements in anthropometry, physiometry, psychometry and on racial psychiatry.

Fifth International Congress for Experimental Cytology

THE fifth Congress for Experimental Cytology will be held in Zurich on August 7–12, 1938. The sixteenth International Physiological Congress and the International Veterinarian Congress will be held in Zurich too, on August 14–18 and August 21–25 respectively. The proceedings of the Cytological Congress are not to be divided in sections, but will be organized in the following way: Scientific sessions will take up seven half days; two afternoons are reserved for demonstrations, and during one afternoon there will be an excursion. Special subjects are to be treated at each session, opening with a general review to which one or two supplementary reviews may be added. Reprints of these papers will be sent to the members of the Congress at their home addresses, or—at the very latest—will be handed over to the members at the opening sessions of the Congress. Copies of the individual papers are likewise to be distributed before the sessions, the main object of this Congress being the discussion of cytological topics of special interest. The following subjects have been chosen for review: epithelium in culture and in the organism; structure of chromosomes; mechanism of mitosis; cancer cells and normal cells; experimental research on cytology and viruses; ultra-structure of the protoplasm and its products; chemistry of the cell. Further information can be obtained from the honorary secretary for the Congress, Dr. Harald Okkels, Institute for Pathological Anatomy, University of Copenhagen, Denmark.

Congress of Anthropological and Ethnological Sciences

FURTHER arrangements are announced for the second International Congress of Anthropological and Ethnological Sciences, which will be held in Copenhagen on August 1–6, 1938 (see NATURE, July 24, 1937, p. 147). This date has been chosen to meet the convenience of any members who may also attend the International Congress of Geography at Amsterdam on July 18–28. The proceedings at Copenhagen will take place in both general and sectional meetings. There will be eight sections, and a number of subsections, each being devoted to some one branch of anthropological study with a special topic proposed for discussion, though this does not preclude the acceptance of communications dealing with other matters. Among the topics proposed, the following may be mentioned: under Physical Anthropology, in the subsection of Anatomy and Biotypology, meeting under Prof. H. M. Houdensen—interrelation of types of fossil man, methodology, and the conception of 'race' in anthropology; Subsection of Physiological Anthropology, under Prof. Oluf Thomsen, geographical distribution of blood groups in man and their presence in animals; in the Section of Psychology, under Prof. Edgar Rubin, influence of the factors of civilization on character and (with the Section of Sociology and Religion) on cultural changes; in the Section of Ethnology, under Prof. Gudmund Hart, origins of agriculture and the domestication of animals and plants; in the Section of Ethnography, in the subsections of Asia and Africa, of which M. C. G. Feilberg, curator of the Ethnographical Museum and M. Carl Kjersmeier are the respective presidents, the nomad pastorals of Asia and Africa; in the subsection of Arctic Ethnography, under Dr. Therkel Mathiassen, the prehistoric and historic culture-movements of the circumpolar region; and in the Section of Sociology and Religion under Prof. Wilh. Grønbech, the extent to which archæology and prehistory can serve as a basis for the study of intellectual development. Applications for membership should be addressed to the Treasurer of the Congress, Nationalmuseet, 10 Ny Vestergade, Copenhagen, K.

National Parks of the Belgian Congo

THE Institute of the National Parks of the Belgian Congo, Brussels, has decided to publish a collection of photographs of the vegetation of these parks, and has commenced by issuing a very fine series of photographs of the general aspect of the vegetation of the Albert National Park, which comprises some 900,000 hectares in the heart of tropical Africa to the north of Ruwenzori and including several volcanoes. The photographs, taken during the expedition of G. F. de Witte (1933–35), are excellent, and they are beautifully reproduced in the first number of this new production (Vol. 1, Fascicules 1 and 2, Plates 1–12, Brussels, 1937): they include some striking examples of arborescent species of *Senecio* and giant *Lobelia*.

Announcements

PROF. James P. Kendall, professor of chemistry in the University of Edinburgh, has given 1,000 dollars to the American Chemical Society for the 1938 American Chemical Society award in pure chemistry. The award, established in 1931 by A. C. Langmuir to encourage creative work in pure chemistry by men of science at the beginning of their careers, will be made for 1938 at the Society's spring meeting in Dallas, Tex., on April 18–21. The age limit, hitherto thirty, has been raised to thirty-five years. Prof. Kendall was professor at Columbia University from 1913 until 1926, and afterwards head of the department of chemistry at Washington Square College, New York University.

A SERIES of two popular lectures by Prof. C. E. Inglis, entitled "Building Big Bridges", has been arranged by the Engineering Public Relations Committee, primarily for those between the ages of 15 and 20 years. The lectures will be given on January 7 and 10 at 3 p.m., at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C.2. Application for tickets, which are free, should be made to the Public Relations Officer, Engineering Public Relations Committee, 1–7 Great George Street, Westminster, S.W.1.

DR. B. L. BHATIA, formerly assistant professor of zoology at the Government College, Lahore, and later principal of the Government College, Hoshiarpur, and author of works on Ciliophora and Sporozoa in the Fauna of British India series, has established "The Science Press of India" as a science news agency for the daily Press in that country. His address is Hotusingh Road, Lahore.

CATALOGUE 15 B (II) of laboratory balances, issued by Griffin and Tatlock, Ltd., contains particulars of a wide range of analytical balances (ordinary, aperiodic, projection-reading, chainomatic) and a noteworthy selection of micro-analytical balances. The catalogue also includes weights, scales and spring balances. A very cheap silica-gel desiccator to replace calcium chloride in balance cases, which lasts indefinitely, is listed.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

Notes on points in some of this week's letters appear on p. 40.

Correspondents are invited to attach similar summaries to their communications.

Fusions between Flexuous Hyphæ and Pycnidiospores in *Puccinia graminis*

In 1933, Craigie[1] discovered that from the mouth of a pycnidium of *Puccinia helianthi* or of *P. graminis* there project not only many straight pointed hair-like cells known as periphyses but also a number of hyphæ which had previously been overlooked and which he called *flexuous hyphæ*; and in *P. helianthi*, some hours after he had mixed the pycnidiospore-bearing nectar of (+) and (−) pycnidial pustules, he observed that some of the flexuous hyphæ had each fused with a pycnidiospore presumably of opposite sex. In 1933, Pierson[2] reported that he had seen similar fusions in *Cronartium ribicola*.

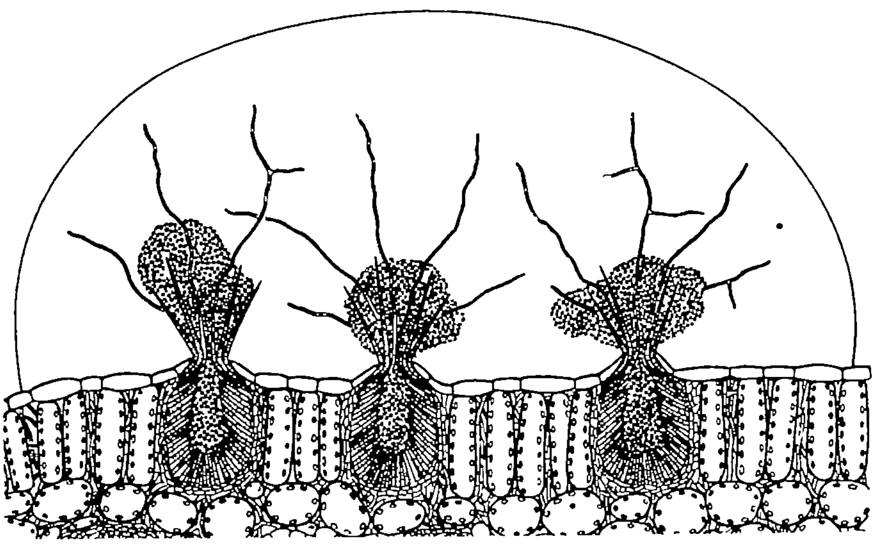

Fig. 1.

Puccinia graminis in a leaf of *Berberis vulgaris*. Vertical section through the upper part of a pycnidial pustule showing: (1) the upper epidermis, the palisade layer, and some spongy parenchymatous cells of the leaf, and (2) some of the intercellular mycelium and three pycnidia of the fungus. The pycnidia are covered by a common drop of nectar into which project from each pycnidium a mass of gelatinous pycnidiospores, pointed periphyses, and several flexuous hyphæ. Highly magnified.

Recently, after mixing the pycnidial nectar of *Puccinia graminis* (the parasite that causes the Black stem rust disease of wheat), I have observed from eighty to a hundred fusions between a flexuous hypha of one sex and a pycnidiospore of opposite sex. No fusions between periphyses and pycnidiospores were seen.

A vertical section through a barberry leaf showing intercellular mycelium and three pycnidia all derived from a single basidiospore of *Puccinia graminis*, and therefore all haploid, is shown in Fig. 1. The main body of a pycnidium is situated beneath the epidermis of the leaf, and consists of a wall bearing pycnidiosporophores from which numerous pycnidiospores are cut off terminally and of a chamber into which the pycnidiospores are set free. The spores have gelatinous walls which swell up and so cause the spores to be extruded at the mouth of the chamber. From the ostiole of each pycnidium is excreted a drop of nectar which, by its scent and sugary contents, is made attractive to insects. In Fig. 1, the three drops of nectar have become confluent. Into the nectar, each pycnidium sends out about 60–70 periphyses (straight pointed red hairs) and a smaller number of flexuous hyphæ, some of which are branched. In Fig. 1 these hyphæ can be seen projecting beyond the clouds of gelatinous spores into the clear part of the nectar.

Several hours after the pycnidial nectar had been mixed, transverse sections of the living leaf and pycnidial pustules were made with a hand-razor, and the sections were at once mounted in water and observed with the microscope. Thus fixing and staining methods were avoided, and the fused hyphæ and pycnidiospores were seen in the living state.

The fusion of a flexuous hypha with a pycnidiospore may take place at the end of a flexuous hypha, as shown in Fig. 2, or at the side of a flexuous hypha, as shown in Fig. 3. In the latter case the flexuous

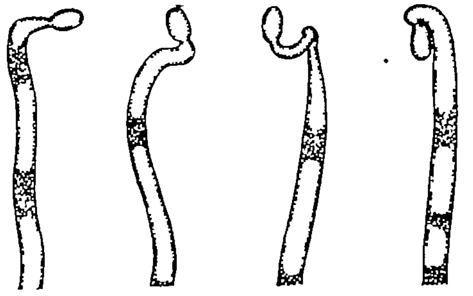

Fig. 2.

The ends of four flexuous hyphæ which have each fused with a pycnidiospore. × about 500.

hypha sends out toward the spore a special branch or fusion peg. Soon after a fusion has taken place (3–6 hours after mixing the nectar), the main protoplasmic contents move out of the pycnidiospore and out of that part of the flexuous hypha which has fused with the spore, thus leaving behind a large vacuole. Presumably the nucleus of the pycnidiospore passes down the flexuous hypha toward the fundaments of the æcidia. This passage is made easier by the fact that the flexuous hyphæ have no septa.

The fundaments of the æcidia or 'rudimentary æcidia' which, after the nectar of (+) and (−) pustules has been mixed, become diploidized and produce æcidiospores, are well-defined haploid organs. They require a special name, and I therefore propose that they should be called *proto-æcidia*[3].

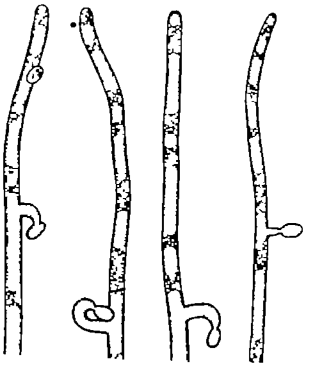

Fig. 3.

FOUR FLEXUOUS HYPHÆ WHICH HAVE EACH SENT OUT A SHORT BRANCH OR PEG WHICH HAS FUSED WITH A PYCNIDIOSPORE. × ABOUT 500.

The experiments here recorded were made early this year at Winnipeg in the Dominion Rust Research Laboratory, and I here wish to acknowledge my indebtedness to Dr. J. H. Craigie for placing the resources of the laboratory at my disposal and to Dr. T. Johnson for supplying me with a series of inoculated barberry bushes.

Nature of the Outer Surface of the Cell Walls of the Mesophyll of the Leaf

IN a recent communication[1], it was recorded that a number of hydrocarbons, including pure paraffin, readily entered the air-spaces of a leaf strip placed vertically in contact with the surface of these liquids, and could also be observed to flow readily over the surface of the exposed mesophyll and cascade down and fill the interspaces. Water, on the contrary, will neither flow over the surface nor fill the interspaces under any conditions, without a pressure gradient.

Since then, working independently, I have found that certain dyes such as janus green, which are also sensitizers of protein monolayers, are strongly adsorbed on the surface of the cells when the leaf is infiltrated under pressure. Under these conditions, it was found that ready infiltration of the air-space could be obtained, but the dye was entirely adsorbed on the cell walls near the point of entry, while the leaf lamina although completely infiltrated by water was entirely free from dye. The dye so adsorbed cannot be liberated by water on exposure of the mesophyll, although it can be extracted by acetone as was described by Ponder[2] for red corpuscles sensitized with brilliant green. The dye cannot be extracted in water by a rise of 15° as recorded by this author for the protein layers of red corpuscles. This possibly may be due to the fact that adsorption took place at a laboratory temperature of 33° instead of 15° as in Ponder's observations on red corpuscles.

Dyes such as methylene blue, neutral red, diamantfuchsin, jodgrun, indigo carmine all give the same results. Other dyes such as orange G, congo red, nigrosin, corallin and magdala red enter the interspaces with the water and show no adsorption.

On using a mixed solution of non-adsorbed and adsorbed dye in approximately equal concentration, the protein adsorbed dye is entirely adsorbed near the point of entry while the other dye enters and fills the interspaces and shows no adsorption. These results are obtained equally well whether the leaf is infiltrated by dye drawn in from the cut edges of the lamina, or whether it is drawn into a complete leaf from the petiole.

If one of the fatty acids such as sodium taurocholate in slight bulk concentration in water be placed on the exposed mesophyll, it begins to spread, and after an interval of one or two minutes the bubbles of air in the interspaces below are displaced and the liquid spreads out and gradually fills the interspaces of the mesophyll. The action is exactly similar to that observed with pure paraffin but the rate is very much slower. Leaf strips placed vertically with the edge in contact with the fatty acid solution are slowly infiltrated, but the process is arrested about 5 mm. from the point of entry, when a brown band of discolouration appears at the limit of infiltration.

The action of the fatty acid on the exposed mesophyll is sensitive to *p*H reactions, as was found by Schulman and Rideal[3] in their observations of the lytic action of fatty acids on protein monolayers in red cells. In this case, the action proceeds readily at a *p*H of 6·2 but very slowly if at all on the alkaline side, while the reverse was recorded for red cells.

The unwettability of these cell walls by water and their great adhesion for hydrocarbons shows that the surface is not covered by liquid water. The strong adsorption of protein sensitizing dyes in general and the non-adsorption shown by other dyes strongly suggest that the outer cell wall–air interface is not a cellulose surface.

The fact that fatty acids which have the power of entering and dispersing protein monolayers cause complete wettability of the walls by water only within certain *p*H values, suggests that the interface may be protein in nature and of molecular thickness.

It is hoped to publish the results shortly.

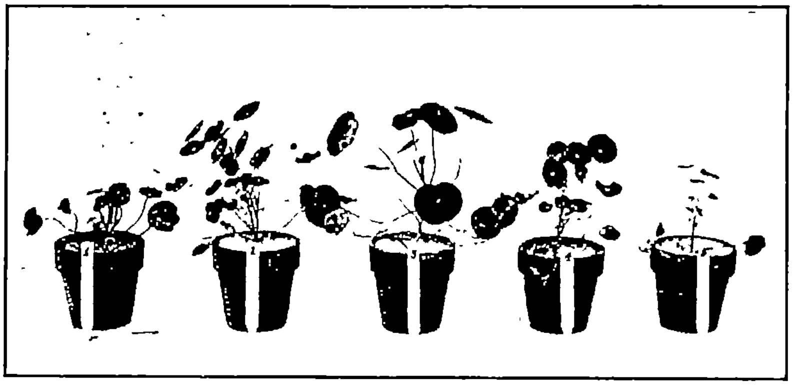
Physiological Curve of Response to Plant Growth Hormones

The addition of growth hormones to a variety of plant materials results in marked responses over appropriate concentration ranges. The behaviour varies with the particular hormone used, the method of application and the developmental stage of the plant. With graded concentrations of growth hormone the response assumes the form of a physiological curve.



Effect of growth hormone on nasturtiums. Left to right: 50 c.c. daily nutrient solution only; same, containing 1/100, 1/10, 1 and 2·5 p.p.m. 1-naphthylacetic acid respectively.

The accompanying photograph shows the characteristic curve obtained with nasturtiums. After fourteen days growth in soil, these plants were transferred to sand in 4-in. pots and treated for twenty-three days in the manner indicated. Marked stimulation in growth at low concentrations is followed by damage as the amount of growth hormone is increased to excess. A physiological curve of this sort is known to be characteristic of the responses which are obtained with a number of different plants, including certain lower plant forms, such as yeast.

Marked increase in the rate of growth is obtained by the addition to the soil of exceedingly small quantities of the active chemicals. The green weight of tops of 8-weeks old lettuce plants was increased more than 300 per cent by the addition of the equivalent of 150 mgm. of 1-napthylacetic acid to an acre. This particular result was obtained by applying appropriate quantities of 1/100 p.p.m. solution at intervals of three days.

The dusting of seeds with growth hormones incorporated in a suitable diluent carrier caused substantial increases in both top and root development. This method of application is particularly advantageous, as it supplies the active chemicals gradually, and avoids the inhibition of root growth which usually results from a solution method of treatment.

A paper on this subject will appear shortly in the *Canadian Journal of Research*.

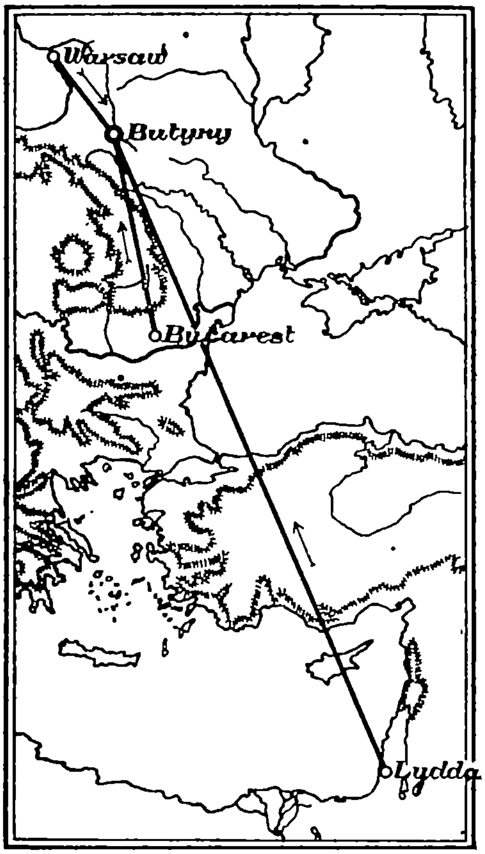
Experiments on Homing in Birds

Experiments on homing in birds were made by one of us[1] for the first time in 1933. These showed that wild birds, especially swallows, have more sense of orientation and are better able to find their homes than even carrier pigeons. Later on, Ruppell[2] established as a result of a series of experiments that swallows could find their homes from distances as great as 1,850 km. The same applies to starlings and wrynecks.

This year we experimented on white storks for the first time. In one test they were taken 50 km. and 111 km. away from Butyny, near Lwów; in another series of tests the birds were transported by aeroplanes (Polish Airways "L.D.T.") from Butyny to Warsaw, Bukarest and Lydda in Palestine, 300 km., 660 km. and 2,260 km. respectively. These distances are all along the airline shown in the map below. The birds were specially marked in bright colours and also ringed, so that it was comparatively easy to recognize them after their return to their nests and young.

The results confirmed that 75 per cent of the birds tested came home safely. The average speed of their journey was one third slower than the speed of swallows over small distances, although it equalled



the speed of swallows over big distances, such as 2,260 km. It should be borne in mind that the flight of the stork differs greatly from that of the swallow. The daily rates of progress did not vary to any great extent. The extremes vary: 165 km. for birds released in Bukarest and 188 km. for birds flying from Lydda.

The behaviour of the birds, when given freedom, was much the same and characteristic as a rule. They all took their time in cleaning and putting their feathers in good order, preparing thus for flight. Having taken to the wing, they circulated above the place where they had been set free for a time which varied practically with every bird, and then every bird took a proper direction for home.

As a result of these experiments we may, we think, regard it as a fact that some species of birds possess a special sense of orientation, which enables them to trace their homes from great distances without the help of kinesthetical factors. It is also not to be doubted that 2,260 km. in a straight line does not constitute the limit from which birds are able to find their homes.

Terminology of Sex Hormones

ONE hesitates to advocate the use of new words, even in a rapidly growing subject such as endocrinology, but obvious anomalies are becoming evident in the description of certain activities of the sex hormones, and there is good precedent for supposing that an improvement in terminology would not only be desirable in itself but also would help to clarify the position. One may recall, for example, that the introduction of the words 'œstrogenic' and 'androgenic' has done much to promote clear thinking and precision of expression. The application of the word 'œstrogenic' to the biological activities of œstrone, and 'œstrogen' to substances having œstrogenic properties, was of course due to the best-known property of the hormone, that of causing changes characteristic of œstrus.

These terms serve a very useful purpose, but it is now evident that they are inadequate. Thus the power of œstrogens to cause feminization of the plumage of birds, especially as hen-feathering is rarely cyclic in the female, can scarcely be called œstrogenic activity. I suggest, therefore, that the word *gynæcogenic* be used as a general term to describe activity which results in the production of the attributes of femaleness, and the word *gynæcogen* to describe a substance having such activity, œstrogenic and œstrogen being applied only to the production of œstrous changes. The capacity of many of the androgenic substances to cause growth of the uterus and mucification of the vagina would then indicate gynæcogenic activity, while *trans*androstenediol, which will cause actual cornification of the vagina, would also be œstrogenic.

Certain properties of œstrone, such as its capacity to correct the castration changes in the pituitary of the male rat, to cause fibrous development of the seminal vesicles or to cornify the uterus masculinus of the rhesus monkey, are difficult to include in any terminology, though the first might be called androgenic activity, and the latter œstrogenic activity if the 'uterus masculinus' of the rhesus monkey is actually a vagina masculina.

A further point concerns the terminology of hormones which have both androgenic and gynæcogenic properties. There is a tendency to refer to such hormones as 'bisexual'. This seems unfortunate, because bisexual has a well-established biological meaning which is quite inapplicable to a chemical substance. Two standard works of reference define the word as meaning "having both male and female reproductive organs"[1], and "having the reproductive organs of both sexes; hermaphrodite; also having sexual feeling for both sexes"[2]. In seeking a more suitable word to apply to a hormone, it may be recalled that Champy[3] introduced the word 'ambosexual' in connexion with plumage and other characters to imply "pertaining to both sexes", and Witschi[4] has used the word 'amphisexual' in a somewhat similar way. A more correct form of the word is apparently *ambisexual*, and it would seem that this could be applied with perfect propriety to substances, extracts and organs which exhibit activities pertaining to both sexes. Thus testosterone would be a hormone with ambisexual properties, possibly, though less correctly, an 'ambisexual hormone', while the testis and the ovary, each having potential endocrine activities related to the function of the opposite sex, would be organs with ambisexual activities.

Finally, reference may be made to 'gonadotropic', 'thyrotropic', etc., which have served a useful purpose for some years and now show signs of becoming indispensable. Burn[5] has recently pointed out that the suffix 'tropic', as used to indicate hormones which stimulate the growth of particular organs, is quite incorrect, and he has since suggested that 'trophic' would be much more suitable. It is clear that the alteration would effect a useful improvement in terminology with little or no trouble to writer or reader, and it is therefore desirable from every point of view. *Gonadotrophic* has already been used by certain investigators[6], and I venture to hope that this form, together with *thryotrophic*, *adrenotrophic*, etc., may become customary.

Faraday on Electromagnetic Propagation

THE significance of Faraday's sealed packet of 1832, opened recently at the Royal Society, is not any potential claim for priority which would be quite foreign to his nature, but the remembrance of an episode of ten years earlier which continued to rankle; he was then suspected of having overheard a discussion at the Royal Institution laboratory about how to produce electromagnetic rotations, which put him on the track of his beautiful solution of that problem and thus produced in fact the earliest electric motor. He was resolved that such suspicion should not occur again. See various indications in his carefully prepared additions in vol. 2 of his "Electrical Papers"; also Clerk Maxwell's trenchant remarks in a reference that has escaped my memory. The scientific interest of the note now revealed lies perhaps in the expression of his conviction that the velocity of propagation of magnetic influence would prove to be small enough to be measurable.

Diffraction of Light by Supersonic Waves in Solids

RECENTLY one of us[1] pointed out that the optical diffraction effects by supersonic waves in solids are to be interpreted on the basis of the Raman-Nath[2] theory, taking due cognisance of the photo-elastic effects arising from the strains caused by the sound waves. A refined further development of this idea enables us now to offer an explanation for a curious effect observed by Hiedemann and Hoesch[3]. Their experiments with glasses show two diffraction patterns of different spacings. With crossed Nicols normal and parallel to the sound-wave, only the pattern with the larger spacing is observed. It consists of the first orders only, with the central one missing. With the crossed Nicols at ± 45° to the sound-wave, only the pattern with the smaller spacing appears, showing many orders, including the central one.

This effect is characteristic for solids. For liquids no diffraction effects appear for crossed Nicols. As Schaefer and Bergmann[4] first pointed out, the existence of two patterns is due to the fact that in solids longitudinal and transversal sound-waves of the same frequency but different wave-lengths can travel simultaneously. Hence the theoretical problem consists in finding the propagation of a light-wave in a medium containing both types of waves.

We can gain an insight into the probable theoretical results by considering first the diffraction effects of either type of waves alone. Since transversal waves travel slower than longitudinal waves, their wave-length λ_T is smaller than λ_L, and the pattern with the larger spacing must be ascribed to the transversal wave. A transversal sound-wave, the directions of oscillation and propagation of which are normal to the light beam, produces a photo-elastic effect characterized by an index ellipse the axes of which are at 45° to the sound-wave. The principle indices of refraction suffer fluctuations μ and $-\mu$ which are equal in magnitude but opposite in phase. If the incident light is polarized parallel to the sound-waves, the two light-components parallel to the axes travel independently and their nth order has components of magnitudes $J_n(2\pi\mu L/\lambda)$ and $J_n(-2\pi\mu L/\lambda)$, where J_n is the Bessel function of nth order, L the width of the supersonic field and λ the wave-length of the incident light. These components are in phase or in opposite phase as n is even or odd. Hence it is easily seen that all even orders, including the central one, have the same polarization as the incident light and are therefore not visible through crossed Nicols. Only the odd orders can appear, in conformity with the observation of Hiedemann and Hoesch. If the crossed Nicols are at 45° to the sound-wave, that is, parallel to an optical axis, the diffraction effect by transversal waves must vanish.

For a longitudinal sound-wave the axes of the index ellipse are normal and parallel to the wave and the index fluctuations μ_1 and μ_2 are in phase but of different magnitude. With crossed Nicols parallel or normal to the sound-wave, the diffraction effects due to the longitudinal wave vanish. If the polarizing Nicol is at 45° to the sound-wave, all diffracted orders are plane polarized, but with a plane of polarization different from that of the incident light. Hence all orders are visible through crossed Nicols, but each order can be made to vanish by rotating the analysing Nicol. In the case of standing sound-waves, the intensity of the various orders passes through a minimum which is different from zero.

These are, of course, preliminary considerations for the development of a more complete theory considering the simultaneous existence of both types of waves. Work along this line has already shown that the diffraction angles φ are generally given by $\sin\varphi = n\lambda/\lambda_L + m\lambda/\lambda_T$, where n and m are integers, but if the light is polarized parallel to the sound-waves, only even m's enter for parallel, and only odd m's enter for crossed Nicols.

Magnetic Moments of the Proton and the Neutron

IT is well known that the magnetic moment of the proton and the neutron cannot be explained by Dirac's relativistic wave equation. It was first suggested by Wick[1] that the surplus moment of the proton may be explained by Fermi's β-theory, according to which the proton spends a certain fraction of its life in a virtual state as a neutron plus a free positive electron and neutrino. Since the electron has a large magnetic moment, this state will contribute considerably to the magnetic moment of the proton. Since, however, the β-decay constant is exceedingly small in nuclear dimensions, it has not been possible to account for the observed momenta in this way.

A new hope for such an 'exchange theory' of the magnetic moments is perhaps offered by the probable existence of a hitherto unknown type of particle constituting the hard component of cosmic radiation. It has been suggested that they are 'heavy electrons' with a mass somewhere between that of the electron and the proton. Since these particles are certainly not stable, it might be plausible to assume that they can be emitted and absorbed by nuclear particles in a similar way as in the β-decay. We therefore assume that, in suitable circumstances, a proton (or neutron) can emit a positive (or negative) heavy electron, transforming itself into a neutron (or proton). Hence it would follow that heavy electrons have no spin and satisfy Bose statistics. In order to account for the magnetic moment of the proton and neutron, it is necessary to choose an interaction between the heavy particles and the heavy electrons depending on the relative directions between the spin of the proton (neutron) and the angular momentum of the emitted heavy electron. Such an interaction can easily be found and has the property that a proton (neutron) with spin in the $+z$-direction can only emit a heavy positive (negative) electron with angular momentum $+1\hbar$ about the z-direction transforming itself into a neutron (proton) with spin in the $-z$-direction. Thus angular momentum is conserved.

The details of this 'interaction *Ansatz*' and their bearing on the nuclear forces will be discussed elsewhere. Without reference to the special type of the interaction chosen, it is possible to calculate the *mass of the heavy electron* from the observed data. Let α be the fraction of time which a proton (neutron) spends in a virtual state as a neutron (proton) + heavy electron and let us assume that the proton satisfies—apart from the above interaction—Dirac's equation; and let M be the mass of the proton, m that of the heavy electron. If we measure all magnetic moments in units of the Bohr nuclear magneton, the magnetic moments of the proton μ_P and neutron μ_N will then be

$$\mu_P = 1 - \alpha + \alpha\frac{M}{m},$$

$$\mu_N = -\alpha - \alpha\frac{M}{m}.$$

Hence we obtain

$$\frac{M}{m} = \frac{\mu_P + |\mu_N| - 1}{1 - \mu_P + |\mu_N|}.$$

Inserting the observed values $\mu_P = 2\cdot 6$, $\mu_N = -1\cdot 75$, we obtain $M/m = 22$ or $m = 80$ electron masses.

This value of m depends sensitively on the departure of the value of the magnetic moment of the deuteron $\mu_P - |\mu_N|$ from 1. But the order of magnitude of ~ 100 electron masses will probably be right. This seems to be quite in accord with cosmic ray data.

Orientation Habit of Martensite

FOR many years, metallurgists have believed that martensite, the hardening constituent in iron-carbon alloys, forms along the octahedral {111} planes of austenite. In 1933, Mehl, Barrett, and Smith[1] reported experimental results which they interpreted as verification of this assumption.

Recently, we have succeeded in demonstrating conclusively that martensite in quenched plain high-carbon steels is *not* parallel to the octahedral {111} planes of the austenite lattice; in fact, the martensite plates are parallel to no low-indices plane of austenite. Actually, the poles of planes delineated by martensite midribs deviate about 2° or 3° from {421} of the austenite lattice; thus, they are not far from the mean cementite-plate orientation determined by Mehl, Barrett, and Smith[1]. Our experimental procedure was, briefly, as follows: Specimens containing large (1–3 mm.) austenite grains saturated with carbon at 1130° C. were prepared (by a suitable annealing treatment) and rapidly quenched from that temperature in a solution of 10 per cent caustic soda. The orientations (to within ½°) of the austenite grains were determined by means of the back-reflection Laue X-ray method; and from a microscopic measurement (and pairing) of martensite midribs on two prepared surfaces, the poles of martensite plates were located stereographically with respect to the orientation of the austenite lattice. Poles of twin bands in the austenite grains, located for check purposes, were found to deviate less than ½° from {111} poles located from the X-ray data.

These austenite grains, which at 1130° C. were saturated with carbon, were found to have, after quenching, a perfect lattice structure with no indication of any distortion, and the martensite midribs in these austenite grains could be measured (that is, were parallel) to within ½°. In specimens having carbon contents appreciably less than the above saturation value, the retained austenite grains have a distorted structure, manifested in a symmetrical broadening of the Laue spots on the X-ray patterns. For all carbon contents investigated so far, the martensite orientation habit is essentially the same. Thus, the martensite transformation in iron-carbon alloys, far from producing a simple octahedral pattern in austenite, actually shows an irrationality in orientation habit comparable to that of the "martensitic transformation" in brass[2].

It is expected that when the complete results of this and collateral work now being conducted at our laboratory become available, it should be possible to give a more comprehensive picture of the interrelation of the various 'constituents' in steel than has been presented heretofore.

The Surface Slit Viscosimeter and the Viscosity of Monolayers

PERHAPS the greatest advantages of the surface viscosimeter which makes use of the flow of a film through a rectangular slit are (1) that the theory is relatively simple, and (2) since there are no moving parts, the substrate, usually water, is not set in motion by the apparatus, but only by the film. In a recent letter in NATURE[1], Harkins and Myers show that the flux of the film through a narrow slit varies inversely as the cube (a^3) of the diameter of the slit. Since this neglects the effect due to the viscosity of the substrate, η_0, it seems to be essential to develop the complete theory, and this has been done by one of us (Kirkwood). For a slit of length l, depth h, and width a, the area flux A, is given by

$$A = \frac{8\alpha a^3}{\pi^4}\sum_{n=1,3,5,\ldots}^{\infty} \frac{1}{n^4\left[\eta + \frac{a\eta_0}{\pi n}\coth\frac{\pi n h}{a}\right]} \qquad (1)$$

where $\alpha = (f_2 - f_1)/l$ is the pressure gradient in the slit. If h/a is large relative to unity, this may be represented by a practically adequate approximation as

$$\eta = \frac{\alpha a^3}{12A} - \frac{a\eta_0}{\pi} \tag{2}$$

The slit viscosimeter is an extremely delicate instrument, when used with small diameters. Expanded films, such as those of oleic, myristic or pentadecylic acid, have very low viscosities, and for their measurement the value of *a* should be 0·1 mm. or less. For 0·1 mm. the correction term is only − 0·00003 surface poises.

The substrate correction, $-a\eta_0/\pi$, is added to the earlier equation. While the highest viscosity (0·0018 surface poises for arachidic acid) given by Harkins and Myers is essentially correct, the lower values are too large by more than the experimental error. The correction applicable to their slit of negligible depth is *smaller* than the term given above, so to insure accurate results the work is being repeated by the use of a slit which meets the demands of the theory.

In the earlier letter, a ring viscosimeter, which vibrates as a torsion pendulum, was described. In addition, there is now in use a surface ring which rotates at a constant rate, either without or with a guard ring, the latter being used to simplify the theory. While theories may be developed for these instruments for the calculation of the absolute viscosity, the theories are somewhat doubtful, so it seems better to calibrate these instruments by the use of the slit viscosimeter.

Sorption of Carbon Dioxide by Chlorophyll

THE interaction of chlorophyll with carbon dioxide is of obvious interest in connexion with the problem of photosynthesis. The formation of an addition product of chlorophyll and carbonic acid has been often assumed to be the first stage in the reduction process.

We performed some experiments to see if solid chlorophyll has any affinity for carbon dioxide. The preparation used was crystalline ethyl chlorophyllide ($a+b$ mixture, 0·3 gm. kindly supplied by Prof. A. Stoll of Basle). It was degassed in high vacuum at 70–80° C. and brought into contact with pure carbon dioxide gas under different pressures. A considerable sorbing capacity was found. The sorption is perfectly reversible, and the equilibrium is established in a few seconds. The sorption isothermals for 0° C. and −80° C were measured out, point by point, in the interval $p=$ 0 to 700 mm. They are perfectly reproducible smooth curves, and can be represented by the sorption formula derived previously[1] for the sorption of gases by crystalline lattices ('zeolithic' sorption). The heat of sorption is 2·6 kcal. per mol, and the saturation corresponds to 2 mols carbon dioxide per mol of ethyl chlorophyllide. The maximum sorption actually observed (−80° C., $p=600$ mm.), was 1·1 mols/mol; at 0° and $p=\frac{1}{4}$ mm. (partial pressure of carbon dioxide in the air), about 1 ethyl chlorophyllide molecule in 15,000 is carrying a carbon dioxide molecule.

The relation of these results to the experiments of Willstätter and Stoll[2] on sorption of carbon dioxide by colloidal chlorophyll solutions will be discussed elsewhere, together with the details of our experiments.

I wish to thank Mr. K. W. Jones for his help in carrying out the experiments.

Mechanism of the Biological Synthesis of Acetylcholine

THE well-known work of Prof. O. Loewi and of Sir Henry Dale and their collaborators has established the widespread function of acetylcholine as a chemical transmitter of nervous action. It has further been established that there exists in the animal organism a specific enzyme, choline-esterase, which effects the rapid destruction of this ester. Interest, therefore, now centres round the mechanism whereby acetylcholine is produced in the body.

Making the assumption that the synthesis in question occurs in nervous tissue, we recently[1] succeeded in demonstrating conclusively that acetylcholine is produced in minced brain from the ox when this tissue is incubated under certain specified conditions. We further obtained some evidence which suggested that acetoacetic acid or one of its derivatives could act as a precursor of the acetyl moiety of the acetylcholine molecule, but the magnitude of the increase in the yield of acetylcholine produced by the addition of sodium acetoacetate to the incubating material was not sufficiently great to justify us in concluding with certainty that this substance acted as an immediate precursor.

Further progress has now been made in the elucidation of this problem. An examination of different portions of the brain by the technique previously described has shown that the synthesis of acetylcholine *in vitro* occurs to a preponderating extent, although not exclusively, in the grey matter, and that rather more is produced by the basal ganglia than by the grey cortical tissue. In view of this result and of the ease with which the basal ganglia can be removed from the remainder of the brain, we have now used this material in place of whole brain for ascertaining the influence of sodium acetoacetate on the synthesis of acetylcholine. The effect of the addition to this tissue has proved to be much greater than was previously observed with whole brain. In experiments which have been repeatedly carried out, the addition of 20 mgm. of sodium acetoacetate to 10 gm. of basal ganglia has increased the yield of acetylcholine, as determined by its action on the dorsal muscle of the leech, by 100 per cent. Further, although smaller, increases are produced by the addition of 10 mgm. of choline chloride.

These results appear to us to demonstrate that acetylcholine is synthesized biologically from choline and acetoacetic acid essentially according to the hypothetical scheme which we previously outlined, although they do not exclude the possibility that minor details of the process still require elucidation. The synthesis is presumably of an enzymic nature, and we are now commencing experiments designed to separate the enzyme concerned from the nervous tissue.

We hope later to give a more detailed account of our work and also to discuss some of the implications of our findings.

A Clay Adjunct to Potato Dietary

IN the course of an expedition to Lake Titicaca, South America, financed by the Percy Slade Trustees in which one of us (H. P. M.) took part, an interesting observation was made in regard to the diet of the Quetchua Indians on the Capachica Peninsula near Puno. These people are almost certainly descendants of the Incas and at the present time live very primitively. They exist largely on a vegetable diet of which potatoes form an important part. Immediately before being eaten, the potatoes are dipped into an aqueous suspension of clay, a procedure which is said to prevent 'souring of the stomach'.

We have examined this clay and found it to consist of kaolin containing a trace of organic material, possibly coumarin, and presumably a decomposition product of the grass from underneath which the clay is dug. The local name for the clay is Chacco, and the Indians distinguish between good and bad qualities. This dietetic procedure is universal among the Indians of the Puno district, and is probably of very ancient origin.

Such a practice by a primitive people would appear rather remarkable in view of the comparatively recent introduction[1] of kaolin into modern medicine as a protective agent for the gastric and intestinal mucosa and as a remedy for bacterial infections of the gut.

Points from Foregoing Letters

A description and diagrams submitted by Prof. A. H. R. Buller show the thread-like flexuous hyphæ of *Puccinia graminis* (which causes the black stem rust in wheat) in the process of fusion with the gelatinous spores of opposite sex (produced in the pycnidia).

Prof. F. J. Lewis finds that the outer surfaces of the mesophyll cells in the leaf, which are unwettable by water but wettable by hydrocarbons, show strong adsorption of protein sensitizing dyes such as janus green. Within certain *p*H limits, protein dispersing fatty acids such as sodium taurocholate render the surfaces readily wettable with water. The author suggests that they are protein in nature and of molecular thickness.

Photographs showing the effect of small amounts of the 'growth-hormone', 1-naphthylacetic acid on 'nasturtiums' are submitted by N. H. Grace. Optimum results were obtained with a solution containing one part in ten millions. Green tops of lettuce plants increased threefold on addition of 150 mgm. per acre.

Experiments made by Prof. K. Wodzicki and his collaborators on the homing of storks have shown that these birds can return to their nests from distances of no less than 2,260 km. in a straight line. It is concluded that there exists a special sense of orientation in some species of birds.

The term 'gynæcogenic' is suggested by Dr. A. S. Parkes as of more general application than 'œstrogenic' in connexion with substances which induce female characteristics, for example, in the plumage of birds. He also recommends 'ambisexual' in place of 'bisexual' and 'gonadotrophic' instead of 'gonadotropic'.

The curious diffraction effects due to supersonic waves in glasses, as observed by Hiedemann and Hoesch, are explained by N. S. Nagendra Nath and Prof. Hans Mueller on the basis of the Raman-Nath theory by taking into account the phase relations of the index variations. New results are predicted concerning the polarization of the light diffracted by the longitudinal sound waves and the existence of new diffraction lines.

In order to explain the magnetic moment of the proton and of the neutron, Dr. H. Frohlich and Dr. W. Heitler postulate the existence of a hitherto unknown particle with a mass somewhere between that of the electron and the proton. From theoretical considerations they calculate for the new particle a mass about eighty times that of the electron. Such particles, the authors state, may constitute the hard component of cosmic radiation.

A. B. Greninger and A. R. Troiano find that in quenched plain high-carbon steels the hardening constituent, martensite, is not oriented parallel to the octahedral planes of the austenite lattice but more nearly parallel to the direction of the mean cementite-plate orientation.

A formula for determining the viscosity of surface films (monolayers) flowing through a narrow slit, developed by J. C. Kirkwood, is submitted by Prof. W. D. Harkins and Prof. J. G. Kirkwood, who indicate the conditions which have to be satisfied.

Solid chlorophyll (crystalline ethyl chlorophyllide) is found by Dr. E. Rabinowitch to have a maximum sorption for carbon dioxide of 1·1 mols/mol at −80° C., under a pressure of 600 mm. At 0° C. and usual concentration of carbon dioxide in the air ($\frac{1}{4}$ mm. partial pressure) the author found about one molecule of carbon dioxide to 15,000 molecules of ethyl chlorophyllide.

Dr. and Mrs. Stedman find that the formation of acetylcholine occurs mainly in the grey matter and the basal ganglia of the brain. They consider that this substance is formed biologically from acetoacetic acid and choline, since the addition of sodium acetoacetate to the basal ganglia doubles the yield of acetylcholine, while a further, although smaller, increase results from the addition of choline.

Research Items

Archaic Culture of the Northern Andes

MM. A. Métraux and H. Lehmann figure and describe (*J. Soc. des Américanistes*, N.S. 29, 1) archaic objects sculptured in stone which were acquired in the course of an expedition to the plateau lands of Bolivia in 1931. Some time was spent at Oruro, where they were advised of the existence of a collection of these objects. They traced them to the village of Belén in the province of Cercado, forty-five kilometres from Oruro. Here similar examples were found sparsely scattered among miscellaneous rubbish, derived from buildings, in a mound in the centre of the village. The mound was about fifteen metres high and about thirty metres long. Other sculptures were found in the walls of adjacent enclosures and buildings, as well as a number of inscribed plaques, some built into the structure of the church. Excavation of the mound was impossible. Much potsherd material was scattered about the mound, but of modern origin. The objects collected, archaic in style, consisted of a number of heads of Felidæ of a varying degree of realism, heads with conventional representations of the human features, a llama, in which the natural form of the stone is merely elaborated, and a number of stones and plaques with geometrical ornament. There is also a figure of a demon. A small number of such archaic sculptures had been recorded previously; but nothing was known of their origin and affinities, beyond that they showed no relation to any known form of Andine prehistoric art. They were evidently intended for affixing to the walls of a building, and with this as a clue a relation with the earliest phase of the Tiahuanaco culture is established. It is therefore concluded on a basis of comparative study that these sculptures represent the most southerly extension of an archaic north Andean culture, and the most archaic phase of Andean sculpture and art.

Economics of Retail Milk Distribution

RETAIL milk distribution has been the object of much criticism on the grounds that it is unnecessarily costly, that the number of retailers is excessive and that wasteful expenditure is involved in competitive advertising and canvassing. Competition, moreover, compels distributors to provide expensive facilities, such as deliveries in half-pint bottles, two deliveries a day and deliveries at special times. Various aspects of the problem are discussed in a useful report by the Food Council on its inquiry into "Costs and Profits of Retail Milk Distribution in Great Britain" (H.M. Stationery Office. 9*d*.). This report examines variations in costs of distribution, profit margins and the possibilities of effecting savings through a more rational organization of the trade. It emphasizes the fact that the overlapping which is inherent in the retail milk distributive industry is responsible for much duplication of effort and in consequence for much expenditure that is uneconomic. Costs are shown to vary considerably owing to differences in 'rounds', dairy costs, advertising and other circumstances and they range, for example, in the case of pasteurized milk from 5¾*d*. to 9½*d*. per gallon among eight provincial co-operative societies and from 9⅝*d*. to 12½*d*. per gallon among seven proprietary businesses in the provinces. The evidence, it is stated, does not suggest that, taking the trade as a whole, profits are substantially in excess of what is reasonable, though a certain proportion of undertakings are making a liberal rate of profit on turnover. It is concluded that to reduce working costs and thus to lower the retail price of milk, it is essential to reduce the number of distributors and to rearrange trade as between one distributor and another, including a concentration of processing and distributing depots.

A Specific Phosphatase in the Nervous System

AN interesting observation recently made by J. Reis (*Enzymologia*, 2, 110; 1937) indicates that the nervous system has a marked ability to break down adenylic acid and its deaminated product inosinic acid. Under conditions where the α- and β-phosphoric esters of glycerol were hydrolysed to the extent of 1 per cent or less, an extract of the white matter of brain hydrolysed inosinic and adenylic acids to the extent of about 40 per cent. This phosphatase is termed 5-nucleotidase, and its action appears to be specific to adenylic and inosinic acids. It occurs both in the white and in the grey matter of brain, in the spinal cord, in peripheral nerve and, to the greatest extent, in retina. A kidney extract proved to be very much less active than an extract of nervous tissue. Magnesium ions have only a small activating action on the enzyme, the optimal activity of which lies between *p*H 7·0 and 7·5. It is probable that so active an enzyme will play an important part in the metabolism of the nervous system.

Adaptive and Constitutive Enzymes

IT is now well known that the formation of enzymes of bacteria may depend greatly on nutritional conditions. A study of these conditions has given rise to the view that bacterial enzymes may be classified as adaptive when they are formed as a response to the presence in the nutritional medium of the specific substrates upon which they act, or as constitutive when they are formed independently of the composition of the nutritional medium. Experiments by J. H. Quastel (*Enzymologia*, 2, 37; 1937) make it clear that this classification may need modification. Working with suspensions of *M. Lysodeikticus*, it was shown that the urease content of the organism increased, not when urea was present in the nutritional medium, but when glucose was present. On the other hand, the catalase content of the organism decreased when glucose was present in the nutritional medium. It appears, therefore, that the enzymes of the cell may be considerably affected by substances, other than their specific substrates, in the nutritional medium. It is pointed out that the enzyme content at any time in the cell must be a function of the rate of its formation and of the rate of its destruction in the cell, and nutritional conditions may affect these rates differently.

Classification of Marsupials

THE division of the Marsupialia into Polyprotodontia and Diprotodontia was originally suggested by Owen and has been widely followed by zoologists. Another classification, based upon the presence or absence of syndactyly, that is, the union of the second and third digits of the foot save for their claws, has been put forward by Wood Jones. Taking both the dental arrangement and syndactyly into account two equivocal families are discovered, the Peramelidæ and the Coenolestidæ. A. A. Abbie (*J. Anat.*, July 1937) has shown that it is possible to use another criterion, and that is the presence or absence of a fasciculus aberrans, an additional, easily recognizable tract in the anterior commissure of the brain. It is found in Diprotodontia but not in Polyprotodontia, and as it is absent in the two equivocal families they are both referable to the Polyprotodontia. The syndactyly of *Perameles* and diprotodontism of *Coenolestes* are regarded as the results of convergence

Goose Hybrids

Two crosses which do not seem to have been noted previously have been described by Einar Lönnberg (*Arkiv f. Zoologi*, 29 B, No. 8; 1937). One is a hybrid between two species belonging to different genera *Branta canadensis* × *Anser anser*; the other between species grouped in different subgenera, *Anser* (*Eulabeia*) *indicus* male × *Anser albifrous gambelli* female. An account is given of the plumage and colour characteristics of the hybrids. The hybrids were raised at Bokenäs on the coast of Kalmar Sound, where the grey lag-geese stock was raised from eggs imported from Sweden and Denmark. The grey lags were allowed to fly freely and some of them migrated and later returned to the place of hatching and upbringing. That the migration journeys were quite extensive was shown by the shooting of one of the marked migrants on the Lower Guadalquivir in Spain, while others were shot in France, Germany and Denmark.

A Land Nemertean in Britain

AN unusual record has been made of the occurrence of a land nemertean (*Geonemertes dendyi*) living in open-air conditions near Swansea, the first known case of the establishment of a land nemertean in the temperate climate of Europe (*Proc. Roy. Soc. Edinburgh*, 57, 379). A. R. Waterston and H. E. Quick describe the external and internal characters of the species, and record the habits they have observed in specimens at large and in captivity. In Nature eggs were laid in March, and in captivity in October, November and April, and hatching took place after about three weeks. The localities inhabited were all damp places, and the worms were most numerous where there seemed to be least interference by man. The species now found in Wales was originally described by Dakin from West Australia, but since then it has turned up in glass-houses in the Botanic Gardens at Breslau in Germany. Like others of its kind, it has suffered unintentional transportation with vegetation or soil carried by man.

Neuropteroid Insects from Formosa

MR. N. BANKS, of the Harvard University Zoological Museum, has recently described a number of new species and identifies others belonging to the orders Psocoptera, Plecoptera and Neuroptera (*Philippine J. Sci.*, 62, 255–291; 1937). It is apparently at once noticeable with these insects, as with others, that the Formosan fauna shows great affinity with the species found on the Asiatic mainland, particularly the highlands. In general the species, and many of the genera, are different from those occurring in the Philippines. The numerous Panorpidæ, the large Sialids, the Raphidias as well as most of the Plecoptera are wholly foreign to the Philippines. These insects show much more affinity with those of Japan, yet Formosa is about three times the distance from Japan that it is from the Philippines. Most of the genera and many of the species are the same as those which occur in Japan.

The Genus *Bathychordæus*

THE genus *Bathychordæus* is one of the most remarkable among the Appendicularia, and hitherto our knowledge of the genus has been limited to the accounts of four specimens from the deep water of the South Atlantic and the Indian Oceans. The fortunate capture of two specimens at Bermuda in a very good state of preservation has enabled W. Garstang (*J. Linn. Soc.*, Zool., 1937) to add considerably to that knowledge. There seems little doubt that these specimens are congeneric with those previously recorded, but they are regarded as belonging to a new species, for which the name *B. styguis* is proposed. They have no Eisen's oikoplasts, no oral glands and no sub-chordal cells in the tail. They do possess Fol's oikoplasts, contrary to what was previously believed. The totality of the structure leads to the suggestion that the type is somewhat archaic, and while showing some affinities with the *Oikopleura fusiformis* group, also shows others with the *Fritillaria* group.

Control of White Plaster Mould

THE fungus *Oospora fimicola* often makes its appearance upon the surface of mushroom beds, where it excludes the more welcome fungus crop. Large white patches are formed, and give to the invader its name of white plaster mould. Messrs. W. F. Bewley, J. Harnett and P. H. Williams have investigated methods for control of this unwanted competitor (*Gard. Chron.*, Aug., 1937). It has been shown that *O. fimicola* does not grow when the acidity of the medium is below *p*H 4·6, and control of its activities has been obtained by removal of infected casing soil, and its replacement by peat saturated with dilute acetic acid. The question as to whether peat alone might be sufficiently acid to control the fungus arises from a consideration of the paper, for many samples of peat have an acidity of *p*H 4·5 or less.

Atomic Weight of Lutecium

HONIGSCHMID (*Naturwiss.*, 25, 748; 1937) has carried out a redetermination of the atomic weight of lutecium by analysing lutecium chloride and finding the ratios $LuCl_3 : 3Ag : 3AgCl$. The sample of the chloride used was found by X-ray spectrographic methods to contain 1·18 per cent of ytterbium, but no other rare earths in measurable quantity. Allowing for this impurity, the atomic weight of lutecium was found to be 174·98. A difference between this value and that obtained by Aston (174·91) by the mass-spectrograph was expected owing to the announcement by Gollnow (*Z. Phys.*, 103, 443; 1936) of the existence of a new isotope of mass-number either 173 or 177 in lutecium. The amount of this isotope, according to more recent work by Gollnow, might be as great as 2·5 per cent. Honigschmid points out that if the isotope has mass-number 177 and is present to the extent of 2·5 per cent, the mass-spectrographic value for the atomic weight of lutecium becomes 174·96, which is close to the chemical value now reported.

Isotopic Composition of Ordinary and Uranium-Lead

THE isotopic composition of uranium-lead is of importance in the determination of the mass numbers of the radioactive elements of the actinium series, the atomic weight of protactinium, the half-life period of actinium-uranium, and the age of the earth. A new determination of this isotopic composition is reported by J. Mattauch and V. Hauk (*Naturwiss.*, 25, 763 ; 1937). Lead chloride prepared from Katanga curite was used for the investigation, and the percentages of isotopes of mass-numbers 204, 206, 207 and 208 were $1 \cdot 1_5$, $24 \cdot 5_5$, $21 \cdot 3_5$ and $52 \cdot 9_5$, respectively. These values are a little different from those obtained by Aston. Assuming a packing-fraction of 1×10^{-4}, and using the correction factors of Smythe, and Mecke and Childs for the ratios $^{16}O/^{18}O$, and $^{17}O/^{18}O$, respectively, the value for the atomic weight of uranium-lead on the chemical scale ($O = 16$) is 207·21. This is identical with the value given in the International Atomic Weight Table for 1937. The isotopic composition of ordinary lead was found to be 95·1 per cent of ^{206}Pb, and 4·9 per cent of ^{207}Pb, giving an atomic weight of 206·01 ($O = 16$).

Illumination of Buildings

FROM the Engineering Experiment Station of the University of Illinois there have recently been issued two papers by Prof. John O. Kraehenbuehl, giving the results of investigations in lighting and illumination. "Problems in Building Illumination" (Circular No. 29) treats of the general principles underlying the necessity for good lighting and the problems met with in obtaining it. The author first discusses the factors involved in 'seeing', a term used to indicate the fundamental relationships between vision and lighting. The human eye was adapted by evolution for long-distance vision and high illumination, but now works under low illumination at close range. Ordinary conditions are 18 in. distance, 3–10 foot-candles and usually considerable glare, and the effect is strain on the muscles of convergence and of accommodation, the symptoms of which are local—such as smarting and watering of the eyes—and reflex—such as headaches and indigestion. From these conditions, the author proceeds to consider illumination requirements and the systems of lighting in use and, in order to show the relationship between the theoretical and the practical aspects of the problem, makes an analysis of several specific examples. In "An Investigation of Student Study Lighting" (Circular No. 28) he gives an account of a survey made of a large number of students' studies. A supplementary investigation of the different types of lighting equipment used in these was made in the Electrical Engineering Laboratory, where a specially equipped room was provided. The methods and material in use were found in most cases to be conducive to eye irritation and unfavourable to concentrated thought. The results, which should be applicable to analogous cases, showed that the most suitable arrangement was a standard indirect lighting fixture placed 30 in. from the ceiling and above the centre of the right-hand edge of the table. Equipped with a 500-watt lamp, this furnished the correct amount of illumination free from glare or shadow on the work surface, and gave, at the same time, the proper illumination to the surrounding walls, this latter being an essential condition for proper eye relaxation.

Babylonian Algebra

IT is now well known that some Babylonian cuneiform texts contain quadratic equations with correct solutions. According to S. Gandz, the word *algebra* is not really Arabic, as generally supposed, but an Arabic form of the Babylonian term *gabru-maharu*, meaning to confront, compare, or set up an equation. Mr. Gandz (*Scientia*, 52, 249 ; 1937) gives further details of Babylonian methods. They did not deal with quadratic equations directly, but approached them by problems concerning rectangles. The first type of problem sought to determine the sides when their sum was known and also the area. A second type replaced the sum by the difference. There were four other types, in which were given the diagonal and the sum or difference of the sides, or one side and the sum or difference of the diagonal and the other side. Mr. Gandz points out that Euclid and Diophantus were influenced by this Babylonian work, and four of Euclid's problems were merely the geometrical form of four of these types. After a time, it was discovered that the six traditional Babylonian types were not exhaustive. Quadratic equations with two positive roots became known, but they were regarded as absurdities, since they gave two values for one and the same quantity. All kinds of devices were employed to avoid them and to keep to the traditional problems of the rectangle, where this difficulty did not arise. It was the great merit of the Arabic School, who taught Europe algebra by the famous treatise of Muhammad ibn Musa al-Khuwarizmi (*c.* 820), that it had the courage to throw over the traditional methods and to replace the six Babylonian types, and all the ingenious devices necessary to employ them, by the three simple and standardized Arabic types. A later age, by the recognition of negative numbers, was able to reduce these to one.

Studies of the Remote Nebulæ

INVESTIGATIONS into the distribution of the distant nebulæ, which are beyond our galactic system, have shown from 'small-scale' sampling that there is a tendency for those nebulæ towards clustering. This observed tendency is believed to be intrinsic ; there appears to be, in fact, an unbroken sequence from double galaxies and multiple galaxies to the meta-galactic clusters and the superclusters. The "Whirlpool" nebula (Messier 51) is an example of a double system ; the great Andromeda nebula with its two satellites (*M.* 32 and *N.G.C.* 205) is an example of a triple system. Such systems provide unique data for studying the relative dimensions of the nebulæ at various stages of the sequence classification, and in certain cases may provide the data for a statistical determination of the relative masses of these star systems. With this end in view, Mr. Erik Holmberg, in *Annals of the Observatory of Lund*, No. 6, has published a catalogue of 827 double and multiple systems, of which only a very small proportion are believed to be merely optical double or multiple systems. The material for the catalogue has come from the author's examination of the important collection of photographs taken by the late Dr. Max Wolf and his successors at the Heidelberg Observatory, Königstuhl. In a preface to the catalogue, Mr. Holmberg discusses some general problems relating to the extra-galactic nebulæ (termed by the Swedish astronomers "anagalactic" nebulæ), as well as describing his procedure in dealing statistically with his data obtained from the Heidelberg plates.

Early Stone Age Cultures of the Great Salt Lake Region, Utah

NO traces of the Folsom culture, the earliest known Stone Age culture of North America, have been found as yet west of the Rocky Mountains. It has been suggested that climatic conditions on the eastern side of the range in early times, possibly so early as the late phases of the Ice Age, were more favourable to human occupation; but the discovery of a primitive culture in caves of the Great Salt Lake region of Utah demonstrates the existence of early man west of the Rockies at a period for which the geological evidence would warrant a very considerable antiquity, possibly in comparative terms not far removed from the close of the Ice Age.

The evidence for this primitive culture is derived from the investigation of caves above the shores of the Great Salt Lake by a joint expedition of the University of Utah and the Bureau of American Ethnology in 1930 and 1931, upon which a report by Julian H. Steward, field director, has been published recently*.

The largest group of caves investigated is situated on Promontory Point on the northern shores of the Great Salt Lake. Another cave at Black Rock on the southern shore was also examined. These caves were once submerged by Lake Bonneville, which at its greatest depth, during the last phase of the Ice Age, stood at a level of one thousand feet above the present level of the Great Salt Lake. A rapid fall in level from the shore-line of this period left its first well-defined terrace, Provo, at no less than three hundred and seventy-five feet below. Further desiccation left only one well-marked terrace, Stansbury, halfway between Provo and the Great Salt Lake, at a point three hundred feet above the latter.

It is with this later terrace, Stansbury, that the earliest of the cultures discovered in the caves is brought into relation. On the assumption that the high-level shore-line dates from the close of the maximum of the final Pleistocene glacial period at about 25,000 years ago, and the Provo terrace from 20,000 years, the Stansbury terrace is assigned a provisional and approximate dating of 10,000 years.

Several caves on the northern shore were examined by members of the expedition, but two only were excavated, and that in part. Of these two, No. 1 yielded artefacts belonging to a single culture of a relatively recent period—1000 A.D. or later. This culture is new and is to be designated "the Promontory culture".

Cave No. 2 is situated much closer than No. 1 to the Great Salt Lake, and in 1931 was sixty-six feet only above water-level. Charcoal and split bones resting on the bedded gravels indicate that it was occupied by man, when the recession of waters first left it habitable, at a date which its position would indicate to have been somewhere between one thousand and five thousand years B.C. It is possible, therefore, that the earliest occupation of the cave may have been contemporary with the Basket-maker I period. The objects of flint and bone found, however, cannot be equated to any known culture; but the paucity of specimens and the limited variety of artefacts make it difficult to define the culture, which at best is impoverished.

The Black Rock cave on the southern shore is 364 ft. above lake-level and 60 ft. above the Stansbury terrace. It must therefore have been habitable some ten to fifteen thousand years ago. No interval appears between the lacustrine gravels and the culture-bearing strata, so that it may be assumed that it was occupied soon after the waters had receded. Evidence of human occupation in the form of charcoal is, in fact, mingled with the gravels. Three more or less distinct periods are represented. The earliest culture, which is associated with an infant burial, lay in the lowest two feet of refuse. Its most significant feature is a complete absence of dart points of quartzite, which are common at higher levels, and the use in their stead of a dart point so minute as to resemble modern arrow points. Other artefacts include knives, scrapers and bone-splinter awls. There is nothing specific to link this cave culture with Signal Butte, Nebraska, Lindenmeier Folsom or Clovis. The greater part of the deposits contains a single culture, the 'Black Rock culture', of which the most conspicuous feature is a distinctive style of corner notched projectile point of grey or reddish quartzite. The leaf-like flint knife appears to be shared by this and the overlying Promontory culture, which constitutes the third distinct element found in this cave.

The paucity of artefacts from the earliest of the cave cultures makes it difficult to attempt, even tentatively, to reconstruct anything like a cultural sequence. Two negative points are to be noted. No single artefact is associated with post-Caucasian objects, and there is little, if any, suggestion of the Basket-maker or Pueblo cultures. Nor is there any great similarity between the Black Rock culture and the early culture of Promontory 2, despite the reasonable assurance that the two were contemporaneous.

It may be stated with certainty that the latest occupants of these caves all belonged to the stage of the Promontory culture. This culture is characterized by the self- and the sinew-backed bow, the reed arrow with hardwood foreshaft, the longitudinally grooved arrow-polisher, "fingernail" and rim-decorated pottery, cedarwood pottery-rests, three- and four-piece mocassins, single rod or rod-and-bundle coiled basketry, triangular flint knives set in wooden handles, and incised slate slabs. It possesses a curious combination of traits of both northern and southern origin; and it is quite distinct from modern Shoshoni, though it may be a form of early Shoshonean. Possibly it is a relic of an Athapascan-speaking people from the north in the course of its migration southward.

Prior to this Promontory culture in the Black Rock cave come the people of the so-called Black Rock culture, characterized most typically by the quartzite dart point, which may or may not be contemporary with Basket-maker and Pueblo, and of uncertain correlation with the early culture of Promontory Cave 2.

The oldest culture of all, preceding the Black Rock culture in the Black Rock cave, has yielded little to characterize it, though its high antiquity appears to be beyond question.

Effects of Impulse Voltages on Transformer Windings

In a paper by Dr. T. E. Allibone, D. B. Mackenzie and F. R. Perry (*J. Inst. Elec. Eng.*, 80, 118; 1937), the results obtained in a very thorough research on the effects of impulse voltages are given.

To understand what is meant by 'impulse voltage' we have to consider the experiments that have been made during the past seventy years. In 1860 Lord Kelvin wrote a paper describing researches that had been made in his laboratory on the voltage required to produce a spark between spherical electrodes. He used primary batteries in series, and obtained some evidence that the spark occurred when the maximum stress between the electrodes attained a definite value depending on the barometric pressure. If higher voltages had been obtainable, he would have found that except when the electrodes were close together and when they were so far apart that brush discharges appeared on them, there was a certain stress at which the discharge occurred. This is definitely proved by the results obtained by several experimenters some fifty years ago. Knowing, therefore, how to compute the sparking voltages between the electrodes in air in certain cases, attempts were made by electrical engineers to determine experimentally the electric stresses that would produce sparking voltages in materials like glass, ebonite, porcelain and even in non-homogeneous substances like the insulating wrappings of cables. Owing to the very high voltages required, alternating current pressures obtained from a transformer were used. This made a very large high-tension laboratory necessary and greatly increased the cost of research at high pressures.

Instead of using a very high pressure transformer, experimenters sometimes employed batteries of condensers. If there were ten such batteries and they were charged to a potential V in parallel, then in series they would give a potential difference of 10 V. But as Kelvin had shown in 1853, this discharge might be oscillatory, obtaining a maximum voltage which is generally taken to measure the maximum stress and then trailing off in a series of smaller oscillations. The effect of the rush of this oscillating quantity of electricity is sometimes deleterious to the transformer windings. As Duddell pointed out many years ago, when a transformer broke down after a rush of electricity through it, the place of breakdown was generally in the windings first subjected to the effects of the rush. Apart from testing, this problem is of vital importance in power transmission lines where we often have inductance and capacity in series, and a neighbouring lightning stroke or a short circuit may start a travelling 'impulse voltage'.

Messrs. Allibone, Mackenzie and Perry have analysed the effects of the applications of impulse voltages of varied wave shapes to transformers. They have considered both single and multiple 'transients'. They have also experimented on model transformers of different winding characteristics and on both single-phase and three-phase transformers. The constants of these transformers must be known as they determine the voltage distribution within the windings due to the impact of a surge. They have been calculated and measured, and the effect of altering them has been examined. The agreement obtained between theory and experiment is good. The transference of surges from one winding to another is considered. They also discuss the testing of transformers with impulse voltages.

In Germany and Switzerland, surge voltages have been used for transformer testing for several years, and this has improved the quality of the transformers. Recently, test schedules have been suggested both in the United States and in Great Britain with the same object in view. The authors conclude that a knowledge of the behaviour of transients in transformer windings is essential if the most efficient use is to be made of the insulation employed. The problem is made more complex owing to the wide diversity of connexions possible between the windings and by the influence which externally connected circuits may have on the transient within the winding. At the same time, as the designer makes research on the impulse voltages within the windings, he must ascertain the behaviour of the insulation employed under a variety of applied impulses, so that by combining the knowledge of voltage distribution with a knowledge of the electric strength of materials, a forecast of the breakdown voltage of the transformer under test conditions can be obtained.

Alloys of Magnesium

MAGNESIUM, the sixth most abundant element in the world, was first made commercially in 1857, and in the last twenty years its price has dropped from 25*s*. to 1*s*. 3*d*. a pound. The recent demand for lightness in construction has led to a great deal of research being undertaken in many countries on the possibility of using magnesium alloys in place of the heavier aluminium alloys as engineering materials, and the results obtained are scattered in many scientific and technical journals. The Metallurgy Research Board of the Department of Scientific and Industrial Research arranged for the results to be summarized by Dr. J. L. Haughton and W. E. Prytherch*.

One of the great limitations to the use of magnesium alloys at the present time is that they tend to corrode very readily in certain types of water, although the corrosion is not always so severe as was originally believed. Much work has been done to find some metal which would notably reduce this trouble, and 0·5–2·5 per cent manganese has an appreciable influence in this direction. Failing further progress in this field, magnesium alloys will probably have to be protected against severe corrosive conditions by paints applied over some chemically produced film, without which paints will not adhere satisfactorily. Special reference is made to the selenium and to the chromate treatment for the production of protective films as a basis for painting, and it is pointed out that the choice of paint to put on the films is important, as many pigments suitable for iron and steel actually stimulate corrosion on magnesium alloys. Reference is also made to the corrosive action of 'leaded' motor and aviation fuels on magnesium cylinders. It is stated that work at the Chemical Research Laboratory has shown that the addition of 1 per cent of quinoline to the fuel inhibits this action and exerts no harmful effect in its anti-knock properties.

---

* Department of Scientific and Industrial Research. "Magnesium and Its Alloys". By Dr. J. L. Haughton and W. E. Prytherch. Pp. viii+100+5 plates. (London: H.M. Stationery Office, 1937.) 2*s*. 6*d*. net.

Owing to the ease with which molten magnesium and its alloys combine with oxygen, special methods have to be employed for melting and casting. With the methods described in the monograph, however, it is stated that there is no difficulty in producing castings in magnesium alloys either in sand or permanent moulds.

The monograph summarizes the mechanical properties at room temperatures of the magnesium alloys at present used in industry. These are almost entirely confined to alloys with aluminium and zinc, often containing a small amount of manganese introduced to improve the corrosion-resisting properties. With alloys containing 8 per cent or more of aluminium, it is usually possible to produce increased hardness and a general improvement in properties by suitable heat treatment. This takes the form of exposure to a temperature of 420° C. for a few hours, sometimes followed by tempering for 4–7 days at about 150° C. Increased ductility can be produced by adding cadmium, and reference is made to an alloy consisting of aluminium, silver, manganese and calcium, which has been found suitable for use in stressed parts at room temperature.

A number of possible uses of magnesium alloys involve the exposure of the metal to elevated temperatures, and for this reason their mechanical properties when hot become important. The results of tests up to 300° C. are given for various alloys. Silver, it has been found, increases the ultimate strength of magnesium up to 290° C. but its effect when used alone is not so marked as that of aluminium. Recently cerium has been added, which is stated to have a pronounced effect in increasing the strength of magnesium at elevated temperatures. Even small quantities, of the order of 1 per cent, have a remarkable effect in increasing the hardness at 300° C. The addition of a small amount of calcium to the cerium-magnesium alloys is beneficial in preventing oxidation during melting and heat treatment as well as in improving the age-hardening properties. The increased hardness due to heat treatment is, however, relatively small, even when calcium is present.

A harder alloy can be produced by adding nickel to the cerium-magnesium alloys, but such alloys were found to be very liable to corrosion. This can be reduced slightly by replacing nickel by cobalt and manganese.

The final chapter of the monograph contains reproductions of all known constitution-temperature diagrams for the alloys of magnesium in the form considered by the authors to be most nearly correct.

F. C. T.

Conditions in the Special Areas of Great Britain

SIR GEORGE GILLETT'S admirable first report as Commissioner for the Special Areas of England and Wales, covering the year ended September 30, 1937, shows no departure from the example of frankness and independence of judgment that was set by Sir Malcolm Stewart. The report is indeed in striking contrast to the evidence tendered by the Board of Trade to the Royal Commission on the Geographical Distribution of the Industrial Population. Like Sir Malcolm Stewart, Sir George Gillett stoutly upholds the principle that the State should control the location of industry, asserting that the introduction of tariffs and quotas has enhanced the Government's responsibility in this matter, and that social and strategic as well as economic causes are driving the Government to abandon the old *laissez-faire* attitude. The recommendations in the recent report of the Import Duties Advisory Committee on the present position and future development of the iron and steel industry, no less than the appointment of the Royal Commission, illustrate this tendency.

The first recommendation is that the conclusions of the British Iron and Steel Federation in regard to all schemes of development of the industry should, whether favourable or not, be reported to an independent body looking to the general public interest. This independent body is to be the Import Duties Advisory Committee itself, and Sir George Gillett points out that this recognition that matters which concern the welfare of thousands of our fellow citizens are properly to be considered in relation to their social and broad economic consequences, as well as in relation to the profit and loss account of the individual concern, marks a great advance.

The second recommendation to which Sir George directs attention relates to the need for dealing with the problem of restoration on a systematic and comprehensive scale to avoid the serious risk of creating extensive areas of broken and barren land by quarrying ironstone over large new areas. Sir George Gillett considers that this touches on one of the vital problems of the Special Areas, and that the recommendations should be extended to apply to all industries, such as the coal, chemical and brick industries, which are apt to leave scars on the landscape, and he suggests that the tragic relics of the past should be avoided by a system of compulsory insurance or by putting responsibility for clearance on the industry as a whole.

As Sir George Gillett points out, the ideal solution is for new industries to be established on sites which have already been scarred and spoilt for any but industrial purposes, as in the huge new steel works being erected by Richard Thomas and Co. on the site of the old works at Ebbw Vale and the new steel works to be erected on the site of the old works at Palmer's Yard in Jarrow. These examples in themselves sufficiently indicate one way in which the problems of the Special Areas are linked up with those of the preservation of amenities generally, but the North Eastern Trading Estate at Team Valley provides a conspicuous example of the way in which industrial development in a new area can be planned so as to add to, rather than detract from, the amenities of the district. Already it appears that proper facilities for manufacture, pleasant conditions for labour and the high advertising value of a well-planned estate weigh quite as heavily with industrialists as economic considerations. Even if the proximity of a fine type of labour has been a further factor, there is still evidence of a real desire on the part of many industrialists to assist in the solution of the problems of this particular Area.

The Commissioner in his report does not hide the difficulties that remain to be overcome or the seriousness of the present situation, but the keynote of the present report is a definite but restrained optimism. During the twelve months, unemployment in the Areas has fallen by 25·6 per cent., of which only a comparatively small part was due to transference out of the Areas, the corresponding figure for the rest of England and Wales being 12·0 per cent. National and international causes have undoubtedly been responsible for most of this improvement, but it has been largely independent of armament work. Another encouraging sign of progress in the Durham and Tyneside Special Area, for example, is the extent to which much of the work necessary for the recuperation of the Area is now in the hands of bodies locally administered and having a lease of life which is independent of Special Area legislation. Further reduction in the volume of unemployment depends upon the success of the measures now being adopted to induce new industries to establish themselves, the further development of those measures and the policy of the Royal Commission.

As regards particular measures, the report refers once more to the question of establishing a calcium carbide factory in South Wales, the investigation of schemes for low-temperature carbonization or hydrogenation of coal, the improvement of communications, and the research carried out by the Technical Advisory Committee of the North East Development Board, while the Commissioner for the Special Areas in Scotland lays a good deal of stress upon the utilization of coke-oven gas as well as the establishment in the Area of one or other processes for the extraction of oil from coal, if any impression is to be made on the most intractable problem—that of continuing unemployment in the coal industry.

For the future, Sir George Gillett insists that it is not so much new organizations that are wanted as twelve months of steady work to see if, with the powers already granted, any impression can be made on the 200,000 unemployed men and women still left in these Areas, of whom about 80,000 are men of forty-five years of age and upwards, many suffering from diseases contracted through working in the coal mines. This is the most significant problem of the Areas, and is being tackled in various ways, apart from insisting on the employment of older men in wage-paid schemes, such as group holdings, subsistence production, voluntary (local amenities) schemes and allotments.

The problem of the Scottish Special Areas is essentially different in the greater difficulty of transference, in the absence of an expanding industrial centre in Scotland, and in the lesser severity of unemployment statistically. There are, however, many towns and communities with every local service, labour suitable for training and employment, attractive amenities, and a robust civic and social sense. Measures to deal with the unemployment in the coal industry have already been mentioned. Among indirect measures, the Commissioner lays stress on housing, land settlement and assistance to schemes for improving water supplies, sewerage and sewage disposal, drainage and the like.

In conclusion, in view of significant omissions in a recent book on the Special Areas, it is pertinent to point out that the present reports indicate that, up to September 30, 1937, estimated commitments, including expenditure on the Special Areas Fund, amount to £12,900,000 in England and Wales and £2,488,584 in Scotland.

Science News a Century Ago

Progress of British Railways

IN the January number of the *Civil Engineer and Architects' Journal*, under the heading "Progress of Railways", were given extracts from various newspapers referring to the state of construction, growth of traffic, etc., on some fifteen railways. Of the Eastern Counties Railway, it was said: "The works of this railway are now pushed as far as Ilford and it is confidently expected that it will be opened to that town (seven miles) next summer." As regards the Grand Junction Railway, it was remarked: "It is said that the Post Office Department have concluded a valid agreement with the Directors, which will enable the inhabitants of Liverpool after the first of May next, to receive their London letters, dispatched on the preceding evening, at eight on the following morning"; and also that "Notice has been given, that it is intended to dispatch a train from the station at Lime street, for the conveyance of pigs to Birmingham". Similar trains were to be dispatched each Tuesday, Wednesday and Thursday. On the Whitby and Pickering line, "A great increase has taken place in the tonnage amount of traffic and numbers of passengers conveyed, the increase in the number of passengers during the half-year had been 8,000, and the increase in goods traffic 6,000 tons". Another notice said, "On the 1st of January, the London and Birmingham Railway will be open as far as Stony Stratford, and also the Birmingham end as far as Rugby, making in the whole 77 miles of this great undertaking completed." The Bolton and Preston Railway had been decided upon, while at a meeting at Penrith of the promoters of the Lancaster and Glasgow Railway, one speaker, when alluding to the western line over Morecambe Bay to Whitehaven, declared that Mr. Stephenson had made a mistake of fourteen miles in computing the length of the line!

Visions of the Extension of the Electric Telegraph

ON January 5, 1838, a correspondent "Inquisitivus" wrote to the editor of the *Mechanics' Magazine* about the electric telegraph, which was then engaging much attention. "It is too often the case", he said, "that the ingenuity and valuable time of talented men are wasted upon what has, unknown to them, been invented before; and of this we have instances in the electric telegraph." After referring to the telegraphs of Alexander, Ritchie, Gauss, Cooke, Wheatstone and Davy, he went on: "Now, Mr. Editor. What shall hereafter prevent our globe from having sets of wire laid down branching in all directions over its surface like the nervous system of the human body, and thus having as it were but one pervading soul?" A patient, in India, he said, could then obtain advice from a doctor in London; the *Sydney Gazette* might contain the proceedings of the House of Commons the day before. "From New York to Pekin, from Pole to Pole, man will be enabled to converse with man, as though he were in the same house, in the same chamber; it will be one step towards making all nations as one family."

Hooker's "Icones Plantarum"

SIR WILLIAM JACKSON HOOKER (1785–1865), the celebrated botanist, had among other works published "Musci Exotici", "Flora Scotica", "Icones Filicum" and his "British Flora", when in 1837 he began the publication of his "Icones Plantarum" containing figures and descriptions of rare plants in his herbarium. Speaking of the last of these, the *Athenæum* of January 6, 1838, said: "This work appears occasionally in parts, each containing fifty plates of new and rare plants, drawn on stone with singular taste and fidelity. Two volumes have appeared, and a third is announced, although it is known to the friends of the author that each volume leaves him a considerable loser. Such a fact . . . is not very creditable to the science of this country. Nothing can be more interesting to a man of science than the plants represented in these volumes; nothing can be in better taste or more faithful than the figures; and it is difficult to conceive how anything can be cheaper (fifty plates for fifty shillings): yet while the most miserable trash that the press produces under the name of Botany sells in hundreds and thousands of copies, such a sterling work as this is only enabled to maintain its ground by aid of the purse of its author. We do trust that the friends of Botany will bestir themselves on this occasion, and come forward with such a demand for copies as will, we do not say encourage, but enable, the learned author to produce many volumes in addition to those which have hitherto appeared."

The Society of Arts

THE *Mechanics' Magazine* of January 6, 1838, said: "The Society of Arts, in years gone by, took a prominent part in the scientific world, and effected considerable good in promoting that spirit of invention and discovery which is now so general among the manufacturing community. It has not, however, kept pace with the times, and has of late fallen into obscurity. It has also fallen into debt, and an appeal has been lately made to its members, urging them to procure donations and annual subscriptions from noble and wealthy patrons of the arts, manufactures and commerce of the country, and to obtain an increase in numbers so as to renovate the funds and extend the useful powers of the Society."

The appeal was issued by the secretary, Arthur Aiken (1773–1854), a chemist and mineralogist who in 1807–14 had published a "Dictionary" of those sciences.

Societies and Academies

Dublin

Royal Irish Academy, November 30.

ARTHUR E. J. WENT: The salmon of the River Shannon. An account is given of the analysis of the stocks of salmon in the River Shannon during the year 1927. The phenomenon of growth in fresh water in the year of migration as a smolt is discussed, and it is suggested that a minimum size is necessary before the physiological condition is attained which causes the assumption of the smolt livery and the smolt migration. Examination of the scales and data from smolts confirmed the results obtained from the examination of the scales of adult fish.

Paris

Academy of Sciences, November 15 (*C.R.*, 205, 885–939).

ROBERT ESNAULT-PELTERIE: The coefficient of self-inductance of a solenoid.

A. PFLUGER: The growth and distribution of the zeros of certain integral functions of positive finite order.

GEORGES VALIRON: A criterion of normal family.

JOHN ELLSWORTH: Photometric study of the variable star *BD*–1° 1004. This star is probably not a variable with eclipses. The photometric period found has no relation with the spectroscopic period.

BERNARD LYOT: The passage of Mercury across the corona.

MIRCEA DRĂGANU: The passage of very rapid protons through matter.

THÉODORE KAHAN: The phenomenon of quantum exchange and nuclear isomerism. A new method of determining this.

GUSTAVE RIBAUD: Improvements in the technique of measuring the temperatures of flames. Modifications of the Kurlbaum optical method.

J. BETHENOD: A method for testing high-power circuit breakers for high-tension systems.

MME. IRÈNE MIHUL and CONSTANTIN MIHUL: The reflection in the atmosphere of waves of radio-diffusion.

MAURICE PARODI: The transmission of some oxides in the extreme infra-red.

ANDRÉ POIROT and MAURICE AUCLAIR: The anode rays of some heavy metals, especially lead. Lead bromide placed in the discharge tube gives satisfactory results and is more convenient than the lead tetramethyl hitherto employed.

ALFRED SILBERSTEIN: Some bromocupric complex compounds.

JACQUES BÉNARD: The parameter of pure ferrous oxide.

C. F. GOODEVE and F. D. RICHARDSON: The existence of chlorous anhydride. Criticism of a recent paper on this subject by Kantzer. This author's method gives an oxide with a spectrum identical with that of chlorine dioxide.

ALEXANDRE TRAVERS and ROBERT DIEBOLD: The mechanism of the decomposition of pure cementite by acids. From a discussion of this reaction it is concluded that it is impossible to determine cementite chemically in a ferrous metal by selective solution of the iron: the carbide is always attacked, liberating carbon, and giving gaseous hydrocarbons.

PAUL CORDIER: The condensation of acetone with phenylpyruvic acid.

Maxence Meyer : The synthesis of a derivative of oxyhydroquinone.

René Hazard, Jean Comandon and Pierre de Fonbrune : The crystallization of ecgonine silicotungstate. Cinematographic registration.

Alexis Lambert : Discovery of the Rhetian with *Avicula contorta* in the Djurdjura chain.

Jean Sagatzky and Rostislav Goloubinow : The origin of the gold on the Guinea-Sudanese border and in the old Haute-Volta.

Emile Miège : Chemical composition of *Triticum*, of *Ægilops* and their hybrids.

Marc Simonet : New pentaploid hybrids in the garden *Iris* (*I. germanica*).

Paul Chabanoud : A new teleostean of the Solidae family, *Pseudaustroglossus annectens*.

Roger Netter and Mlle. Simone Roche : The action of hydrochloric acid upon insulin.

Marc de Larambergue : Genetic study of *aphallie* in *Bulinus* (*Isodora*) *contortus*.

Brussels

Royal Academy (*Bull. Classe Sci.*, 23, Nos. 8–9, 1937).

G. Goethals : The synthesis of Δ 2–6 octadiene-1-al. This aldehyde was prepared from pentenyl chloride by converting it into pentenyl vinyl carbinol and acting on the latter with phosphorus tribromide. Octadienyl benzoate was prepared from the bromide and then saponified. The octadienol so produced gave the octadienal on oxidation with chromic acid. The Raman spectra of the primary and secondary bromides formed in the above reactions were examined as a means of identifying the products.

B. Ruyssen and E. Verstraete : Complex coacervation of the system gelatine-saponin. Determinations of the viscosities of mixtures of these colloids as a contribution to the study of complex coacervation, an intermediate stage in the flocculation of hydrophilic colloids in which the initial desolvation is caused by the opposition of the electrical charges on the two components of the mixture.

J. D. H. Donnay : Morphology of apophyllite. A discussion of the true crystallographic symmetry of this mineral and its representation.

Cracow

Polish Academy of Science and Letters, November 8.

S. Dobinski : The adsorption of the components of a solid phase at the surface. The examination, by means of electron diffraction, of the surface structure of certain metallic alloys, shows that the concentration of the components in the neighbourhood of the surface is not identical with that corresponding to the deeper layers. This is possibly due to the effect of surface tension.

J. Wesolowski : The dielectric polarization of liquid selenium. From experimental results obtained with an apparatus capable of measuring the dielectric constant with an accuracy of ±0·5 per cent, between temperatures ranging from 237° C. and 300° C., it is shown that the atomic polarization is 12·0, is independent of the temperature, and satisfies the rule established by Cuthbertson and Doborzynski.

Mlle. L. Stankiewicz : The arithmetical operations in the calculation of determinants according to Cracovian methods.

I. N. Konovalov: An experiment in vernalizing the embryos of wheat seeds without endosperm.

Washington, D.C.

National Academy of Sciences (*Proc.*, 23, 535–559, Oct. 15, 1937).

C. C. Little and A. M. Cloudman: Occurrence of a dominant spotting mutation in the house mouse. A new mutation has been found, probably an allele of the dominant spotting already known and more viable in the homozygous condition.

E. W. Berry: Succession of fossil floras in Patagonia. Following the Late Jurassic cosmopolitan floras, conditions during Lower and Upper Cretaceous did not prevent colonization by elements representing Upper Cretaceous flowering plants. Early in the Tertiary, a change occurred which allowed a flora of small-leafed and largely beech forest (Eogene) to extend down to Antarctica.

B. H. Willier, Mary E. Rawles and E. Hadorn: Skin transplants between embryos of different breeds of fowl. Skin ectoderm (0·5 mm. × 1 mm.) was taken from the dorso-lateral surface of the head, freed from mesoderm, and inserted, through a window cut in the shell of another egg, at the base of the right wing or the leg bud; both donor and host were incubated for about 75 hours. The embryos were examined when 15 days old, when they have well-developed down feathers. Black skin grafts give a patch of black feathers, but white skin grafts on a black breed have no apparent effect. It seems that skin ectoderm is dependent on the position on the host for the form of feathers produced, but as regards colour, the feathers are dependent on the genic constitution of the graft.

A. D. Michal: General projective differential geometry.

G. A. Miller: Groups in which every sub-group of composite order is invariant.

H. S. Vandiver: (1) The concept of co-sets in a semi-group. (2) Generalizations on the numbers of Bernoulli and Euler.

Forthcoming Events

Friday, January 7

Engineering Public Relations Committee (at the Institution of Electrical Engineers), at 3.—Prof. C. E. Inglis, F.R.S.: "Building Big Bridges" (Christmas Lectures for Young People. Succeeding lecture on January 10).

Conference of Educational Associations, January 3–10. To be held in University College, London.

The Right Hon. Sir Kingsley Wood, M.P.: "Education and Health" (Presidential Address).

Geographical Association, January 4–6. Annual Conference to be held in the London School of Economics.

January 4, Prof. Patrick Abercrombie: "Geography, the Basis of Planning" (Presidential Address).

Annual Exhibition of Scientific Apparatus by the Physical Society, January 4–6. To be held at the Imperial College of Science and Technology, London.

Discourses:

January 4, Capt. G. C. C. Damant: "Diving in Deep Water and Shallow".

January 5, Prof. A. F. C. Pollard: "Mechanisms for Measuring Small Changes".

Science Masters Association, January 4–7. To be held in the Chemistry Department of the Imperial College of Science and Technology, South Kensington, S.W.7.

January 4, Sir Cyril Ashford: "Past and Future Aims of School Science" (Presidential Address).

January 5, Sir Richard Gregory, Bt., F.R.S.: "Science and Citizenship".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant Lecturer in Aeronautics in the Imperial College of Science and Technology, Prince Consort Road, S.W.7—The Secretar (January 7).

Research Chemist (subsidiary subjects physics or metallurgy) fo the Northern Coke Research Committee—Secretary, Northern Cok Research Committee, King's College, Newcastle-on-Tyne.

Training and Employment of University Graduates

IF happily unemployment of graduates is less serious in Great Britain than in some other European countries, it has been sufficiently widespread to offer obstacles to the work of the Society for the Protection of Science and Learning in finding occupation for displaced men of science from abroad, apart from the existence of a by no means negligible amount of wastage and misplacement of young graduates of our own universities. Indeed, the position led the University Grants Committee in its last report to suggest that the universities themselves should consider not merely the question of the appropriate number of university students in relation to the population of the country as a whole, but also that of the appropriate number for any particular university. Granting that a university should not be too preoccupied with problems of purely professional vocations for its students, it should none the less face the question whether the time has arrived, or is approaching, when additions to its numbers will tend to impair the quality of the instruction and the value of the training for life it sought to give.

For these reasons, the inquiry on unemployment among graduates, and the study of the proposals for diminishing unemployment in intellectual professions, which has already been initiated by the Committee on Intellectual Co-operation of the League of Nations, is of no less interest in Great Britain than elsewhere; while W. M. Kotschnig's recent study of unemployment in the learned professions* is also a valuable contribution. The case he presents for real educational and occupational planning in our changing society as the only solution of this difficult problem deserves careful consideration, reinforced as it is from other quarters of the industrial world by the suggestion that industry should consider more closely not merely qualitative but also quantitative requirements in regard to recruitment generally.

It can scarcely be denied that neither the universities nor professional associations of scientific workers, despite serious warnings, have given anything like the attention to this question that it demands. The report on graduate employment recently issued by the National Union of Students, to which reference was made in discussions at the British Association meetings at Nottingham, brings together in this field a number of suggestions or proposals which require attention and action by professional associations as well as by university authorities.

This report, which brings out the fact that in Great Britain the question of misemployment among graduates is as important, if not more important, than that of actual unemployment, reveals the meagreness and inadequacy of existing statistics and the complete absence of planning or control over the numbers entering various branches of study, as well as the ignorance on the part of students proceeding to a university of conditions in the employment market. The most serious criticism in the report is, in fact, that of the lack of guidance and help available at the universities for placing students in careers. Even where appointment boards or officers are to be found, their organization often leaves much to be desired. Contact with students is imperfect, and with industry, commerce and the professions is often poor.

Many who have attempted to recruit university graduates, particularly for any of the less usual openings, will agree that much of this criticism is well founded. It is no uncommon experience to find that after approaches to the universities appointments boards or advertisements in the appropriate scientific or technical journals have drawn blank, promising candidates have been encountered accidentally, who, like the professors of their particular faculty, were quite unaware of the existence of the vacancy. Quite apart from the fact that the outlook of graduates on the sphere of employment is often unnecessarily narrow, such experiences are common enough to indicate not merely the failure of graduates to look round them intelligently but also an amazing lack of contact between the appointments boards and the different faculties or departments the students of which it is their function to place.

---

* London: Oxford University Press, 1937. 12s. 6d. net.

There can, of course, be no question of value of the appointments board when well organized and properly run. An efficient board rapidly builds up a reputation for supplying candidates of the right type; and this is as valuable to the employer as to the graduates it places. Accordingly, the highly constructive suggestions in this matter, which are outlined in an appendix to the report referred to, merit close attention by all concerned with the placing of graduates in employment; for the establishment of efficient appointment boards must inevitably precede the consideration of the quantitative aspect of the question. These suggestions show clearly that at the present time the problem is not so much one of finding posts for graduates but of finding graduates to fill the existing vacancies.

One of the first results of a really efficient appointments organization would be not only to co-ordinate the spasmodic and often haphazard recommendations and efforts of individual professors and teachers, and to promote the supply of candidates in whom due weight was given to the other qualities besides the academic which they possess, but also to facilitate the collection of accurate and comprehensive information. The functions of the organization should, in fact, include a survey of the whole field of potential employment for university graduates, and the establishment and maintenance of contact with employers' associations, professional institutions and organizations and the like.

Information regarding the qualifications and personnel required for different careers, as well as of the nature and conditions of the work, salary scales and prospects, is frequently readily obtainable, but corresponding information regarding the overcrowding of a particular occupation, new developments and tendencies is often deficient and inaccurate, and in many places the means of making even the existing information really available to students early in their university career appear to be in need of improvement. It is suggested, accordingly, that a handbook on the lines of the "Handbook on Careers for Graduates and Students", which is published by the University of London Appointments Board, might be issued by each appointments board.

Obviously there is room in this particular field for effective co-operation between the appointments boards of different universities. Even if certain universities desired to expand the information regarding the particular occupations for which they specially prepare students, there would appear to be no reason why such a handbook should not be prepared on behalf of all the universities. Not only should a mere comprehensive handbook be obtainable in this way, but also co-operation should offer substantial financial savings.

Whether there is need for the different sub-committees suggested in the report to deal with technical appointments, teaching, professional, Government appointments and commerce, etc., may well be a matter of opinion. Much depends on obtaining men of the right type of personality, mature experience and with something of a flare for establishing contacts to serve the board. Appointments officers of the right type could probably be relied upon to take care of the requisite internal as well as external contacts, though it may sometimes be advisable for the university to institute some means of stimulating the use of the machinery provided in the boards' organizations, so as to bring together all those interested in placing graduates whether of a special faculty or not.

As to the wisdom of the further suggestions regarding contact between students, and between the appointments officers of different universities, there can scarcely be any difference of opinion, though there are other ways of securing contact with students than by representation on the boards. Such co-ordination and organization are essential if statistical information is to be collected in standardized form on the numbers of students in each faculty, the potential output of the university for different careers and the numbers of students leaving or who have left the university, and the nature and extent of unemployment among them.

Valuable, however, as are such statistics as a preliminary to planning the wiser use of university education on the community, we must guard against the mistake of allowing the university authorities or the students themselves to be preoccupied excessively with the professional prospects of later life. The effective employment of university graduates is a matter of much moment to the community as a whole as well as to the individuals concerned, since the appropriate use of talent to a large extent governs the pace of social progress. This is one reason for regarding with concern the comparative neglect of university graduates in the local government service of the country. None the less, we must be at pains to reconcile the objective of the best training for a vocation in life with that of the best training for life itself.

Once again, therefore, we are brought back to the question of the true purpose of a university, and even here it seems that a university appointments officer might well make a valuable contribution. His contacts with the industrial and commercial world should enable him to supply timely warning about the evils of premature or excessive specialization, and to insist on the need for men and women with a wide outlook, sense of values and cultural interests so strongly stressed in recent discussions. It should enable him too, perhaps, in his contact with students, to inspire them with a sense of responsibility for service which, by bringing out the fundamental meaning of vocation, may rob vocational training of its dangers. Nor should he lack the opportunity to give timely warnings as to the importance of cultivating human interests and utilizing to the full the opportunities which the social and athletic activities of college life afford of developing initiative, personality and the capacity to cooperate, upon which, as much as on intellectual attainment, depend alike individual success and the fullest meed of service to the community.

Growth-Regulating Substances in Plants

Phytohormones
By F. W. Went and Kenneth V. Thimann. (Experimental Biology Monographs.) Pp. xi+294. (New York: The Macmillan Co.) 17*s*. net.

THIS book will prove very valuable as it reviews admirably a field in which the contributions have recently been so numerous that it is difficult to follow them all. (The authors give references to seventy-four papers on plant hormones for 1936 alone.) This rapid output is no doubt due to the discovery by Kögl and Kostermans (*Z. physiol. Chem.*, 235, 201) in 1934 that indole-3-acetic acid, sometimes called 'heteroauxin', a substance which can be synthesized, acts on plant growth in very nearly the same way as the natural growth-hormone or 'auxin': for this has provided wonderful opportunities for experimenting. But unfortunately, as the authors point out, the quality of some of this recent work has not been so good as that of the earlier work on the growth-hormone: indeed, some recent contributions have shown that the investigators responsible for them neither know what has been done already nor understand what are the problems at issue. The book should, therefore, be very useful, since it reviews critically the subject of the hormones of higher plants and shows up the main problems clearly: indeed it is one of the chief attractions of the book that it looks to the future as much as to the past. The authors include also summary statements of many interesting unpublished results, and although an excellent historical survey of the same field by Boysen Jensen entitled "Die Wuchsstofftheorie" appeared in 1935, progress has been so rapid that they have been able to include a great deal that was not in the earlier book.

Boysen Jensen has claimed ("Die Wuchsstofftheorie", p. 12) that in his well-known experiments of 1910, 1911 and 1913, from which the modern study of the growth-hormone has mainly developed, he proved that there exists a growth-promoting substance in the oat coleoptile during the phototropic excitation, and that it is by the movement of this substance that the phototropic stimulus can be transmitted (as he showed) from the tip across a watery gap below. In the reviewer's opinion, this claim is justified, except that, as Went and Thimann point out, he did not show that he was dealing with a single growth-promoting substance rather than with several substances. But neither did the later experiments of Paál (*Ber. bot. Ges.*, 32, 499; 1914; *Jahrb. wiss. Bot.*, 58, 406; 1919) show that the growth-hormone is a single substance, in spite of what Went and Thimann say (p. 11). The important point which was missed by Boysen Jensen but established by Paál and by Söding (*Ber. bot. Ges.*, 41, 396; 1923) is that even the tips of *unstimulated* coleoptiles form growth-promoting substance (or substances), and it was not generally agreed that it is a single growth-substance which they form, until this substance, now called 'auxin', was extracted and studied by Went himself (*Rec. trav. bot. Néerl.*, 25, 1; 1928). Later work has shown that this auxin is the same growth-substance which was demonstrated by Boysen Jensen, and it has been found that auxin regulates a surprising number of other growth processes also.

The authors are a little misleading in saying that Dostál (*Acta Soc. Sci. Nat. Moravicae*, 3, 83; 1926) interpreted his experiments on the correlative inhibition of axillary buds "in terms of nutrition and water relations, like his predecessors": for this gives the impression that he interpreted them in terms of a withdrawal of nutriment or water. But actually he attributed the inhibition to an effect upon the buds of metabolic products coming *from* the leaves, an opinion not very different from the recent discovery that it is the auxin secreted by the young leaves which somehow brings about the inhibition of axillary buds.

The investigations reviewed in this book have progressed quite along the lines advocated by Roux for animal embryology. First came the recognition of various 'complex components' in plant growth, and the discoveries that they depended on transmitted influences of unknown nature; among such 'complex components' were the growth-reactions of the tropisms, the initiation of cambial growth and of root-formation, and the promotion of the growth of coleoptiles and shoots. Next came the evidence that the influences on which these processes depended could cross watery gaps and were due to the movements of a soluble substance or substances. Later again came the extraction of the substance concerned and its identification as auxin. The next step must be to discover more in detail the manner in which the auxin acts, and thus to continue the analysis in the hope of reaching finally the basic molecular or ionic reactions. But when, or if, these are discovered, a knowledge of the foregoing analysis will still be necessary for anyone who wishes to understand plant growth.

West African Plant Lore and Uses

The Useful Plants of West Tropical Africa

By Dr. J. M. Dalziel. Being an Appendix to the "Flora of West Tropical Africa" by J. Hutchinson and J. M. Dalziel. (Published under the authority of the Secretary of State for the Colonies.) Pp. xii + 612. (London: The Crown Agents for the Colonies, 1937.) 18*s*.

THE series of Colonial floras issued from the Royal Botanic Gardens, Kew, are highly technical works of great value to the systematic botanist and to the trained worker in the countries in question. But there is much information of economic and human interest which lack of precise information and consideration of space has perforce to be omitted. Dr. Dalziel's volume is an attempt to fill this gap in our knowledge of the West African flora as a supplement to the "Flora of West Tropical Africa" recently completed by Dr. Hutchinson and himself.

Dr. Dalziel was especially well qualified for the task. His long service as a medical man in the British West African Colonies, his knowledge of the flora and his interest in native customs and languages—he is the author of "A Hausa Botanical Vocabulary"—have yielded a mass of information collected personally. This has been supplemented from notes on herbarium specimens and from literature, especially the published work of Dr. A. Chevalier and his colleagues on French West Africa, which covers the greater part of the area dealt with.

Care has been exercised in the selection of vernacular names, which are notoriously difficult to collate with certainty. These are classified geographically and according to local dialects, and though in some cases open to revision may, as the author points out, become important where a Colonial administration seeks to fix official names for commercial timbers or noxious weeds.

Obvious characters of the species included are described as well as their domestic, medicinal and commercial uses, but it is assumed that the volume will be used in conjunction with the "Flora", the arrangement of which it follows as regards the families, under which genera and species are arranged alphabetically. The numerous references to relevant literature in the text are supplemented by a general bibliography which is additional to that included in volume 1 of the "Flora".

A detailed index of the vernacular names covers forty-three closely printed pages, and there are also indexes of common English and scientific names.

Dr. Dalziel's volume is an invaluable contribution not only to our knowledge of the economic botany of West Africa but also to its ethnology.

Recent Developments in Probability Theory

(1) Généralités sur les probabilités; variables aléatoires

Par Prof. Maurice Fréchet. (Traité du calcul des probabilités et de ses applications, par Émile Borel, Tome 1 : Les principes de la théorie des probabilités, Fascicule 3 : Recherches théoriques modernes sur la théorie des probabilités, Livre 1.) Pp. xvi + 308. (Paris : Gauthier-Villars, 1937.) 90 francs.

(2) Théorie de l'addition des variables aléatoires

Par Prof. Paul Lévy. (Monographies des probabilités, Fascicule 1.) Pp. xvii + 332. (Paris : Gauthier-Villars, 1937.) 120 francs.

(3) Random Variables and Probability Distributions

By Prof. Harald Cramer. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 36.) Pp. viii + 121. (Cambridge : At the University Press, 1937.) 6*s*. 6*d*. net.

(4) Les lois des grands nombres du calcul des probabilités

Par Prof. Louis Bachelier. Pp. vii + 38. (Paris : Gauthier-Villars, 1937.) 18 francs.

(1) PROF. FRÉCHET'S "Généralités" represents the first volume only of a treatise which, as a whole, is to form part of the very important "Traité du calcul des probabilités" edited by Prof. Borel. The present volume is chiefly dedicated to an examination of the theory of random variables which has both simplified and re-modelled the classical theory of probability.

The volume is divided into two parts, the first of which consists of a general introduction to the theory of probability and a short chapter on various extensions of the principle of total probabilities. In the second part, Prof. Fréchet considers the mean values of random variables and proceeds to an examination of the inequality of Bienayme and its generalizations. But perhaps the most interesting work is contained in sections III, IV, and V of his chapter on different methods of convergence for a series of random variables. For here, the connexion between Prof. Fréchet's brilliant work in general analysis, including the theory of abstract spaces for which he is justly famous, and his contributions to probability theory, is clearly exhibited. In these sections of Chapter v, Prof. Fréchet considers all those random variables x which are definable in a given category of tests as the same number of points in a certain abstract space. He then proceeds to examine the various definitions of the limit of a series of random variables, to find that each of them completes the definition of a 'space' containing such random variables, and that the spaces thus defined are not identical. The whole work shows the close connexion of these developments with the order of ideas dominating general analysis.

(2) Prof. Paul Lévy's book is the first of a series of monographs destined to supplement the "Traité" of which Prof. Fréchet's work forms a part. Prof. Lévy is the author of an earlier work on the calculus of probabilities, and in this monograph he includes original work of his own as well as a survey of the most important problems and their solutions, where these have been forthcoming. He observes that, during the last fifteen years, research in the calculus of probabilities has made tremendous advances, and that problems born of the theory of probabilities of denumerable order have been discovered, for which, in a number of cases, solutions have been found. His own work during recent years has been principally concerned with the study of asymptotic problems relative to probabilities, a branch which owes much to the work of Kolmogoroff and Khintchine, who are also responsible for the fundamental results obtained from the study of series of which the terms are independent random variables. The latter are examined in Chapter vi of the present volume. Prof. Lévy further attributes to the work of Khintchine and his pupils the completion of his own study of integrals, the elements of which are independent random variables.

After a short general exposition of the foundations of the calculus of probabilities, Prof. Lévy devotes two further introductory chapters of a mathematical character to the examination of the theory of random variables and the law of probability, in close connexion with the theories of measurement and the Lebesque-Stieltjes integral. Throughout the whole work, Prof. Lévy is really concerned with the translation of the theorems of general analysis into the language of probability. He advocates practice in this exercise, so that the enunciation of a theorem in one language should automatically evoke the parallel enunciation in the other.

(3) Prof. Cramer's little book published in English as a Cambridge Tract has many points of contact with Prof. Lévy's larger work. He treats the subject, mathematically, as a branch of the theory of completely additive set functions and thus chooses his axiomatic foundations in agreement with those of Kolmogoroff. For the most part, Prof. Cramer avails himself of the method of

characteristic functions, a method which Prof. Lévy had once hoped to be able to reject in favour of the utilization, wherever possible, of more elementary arguments. Although he is apparently still of the opinion that it may some day be possible to dispense with this method, Prof. Lévy considers that for the advanced part of the theory, a familiarity with Fourier transformations and the properties of characteristic functions is essential.

Although in Part II of this brochure Prof. Cramer shows how many of the results for distributions in a one-dimensional space R_1 can be extended to spaces of any number of (finite) dimensions, he is unable here, for lack of space, to consider probability distributions in spaces of an infinite number of dimensions. This is naturally a restriction in the proper treatment of modes of 'convergence in probability'. Again, in the advanced part of the theory, Prof. Cramer finds it expedient to confine himself to the treatment of problems connected with the central limit theorem for sums of independent variables.

(4) Prof. Bachelier's brochure on the laws of large numbers has for its object the study of these laws in a more complete form than has been usual in the majority of treatises, in which they have been considered only in the simplest cases. In Prof. Bachelier's own larger work on the calculus of probabilities, these laws were treated as consequences of a more general theory, but here he deems it useful to isolate them from all analytical apparatus.

One of the principles of the more general theory to which he alludes is the supposition of the continuity of all variables, and in particular of that variable which expresses a series of exceedingly numerous tests. By means of this assumption, this variable permits of being assimilated to time; in consequence, the transformation of the probabilities in a series of tests appears as a continuous phenomenon. The whole content of this work is rigorously exact in accordance with the hypothesis of continuity, and the main object is the application of the results to problems which are, in reality, related to discontinuous variables. A. v. Z.

Practice and Principles

Belief and Action:
an Everyday Philosophy. By Viscount Samuel. Pp. 366. (London, New York, Toronto and Melbourne: Cassell and Co., Ltd., 1937.) 7*s*. 6*d*. net.

THIS ably and attractively written book is wholly in accord with much that has recently appeared in the columns of NATURE. For while the author is convinced that we must find "a way out from the intellectual anarchy of our time", he is equally definite as to the contribution which science can offer towards this end. Neither mysticism nor intuition, merely as such, can solve our problems; rather must both be criticized, and often corrected, by reason. This, however, involves neither "intellectual pessimism" nor crude materialism; on the contrary, "Science makes a spiritual view of the universe more tenable" and is, indeed, perfectly compatible with worship.

Still more significant is the application of this point of view to practical affairs. Although he advocates no extremist measures which may worsen the disease, Lord Samuel insists that economic injustice is widespread and destructive. But machinery is not the cause of this; for man's slavery to the merely material aspects of life could be removed by its further expansion, were this but properly directed, though this ideal involves "testing the very foundations on which civilization rests". But here again "history must be handled scientifically", exactly as with politics, economic and eugenics.

Discussion of more abstract themes has wisely been relegated to appendixes dealing with reality and value, matter and mind, causation, indeterminism and freedom. The treatment of the implications of the uncertainty principle is exceptionally clear; Viscount Samuel follows Planck, Einstein and Rutherford in their rejection of indeterminism, inherent in Nature, as distinct from that which is but the inevitable result of limited knowledge. This is no purely theoretical question; if "at the heart of Nature hazard rules", then all large-scale planning may prove quite futile.

Such a determinism, still further, forms the only reliable basis for any sound ethics. Well-being is indissolubly linked with good; pain and penalty with evil. But equally essential to morality are genuine choice and personal freedom, attainable only when the individual becomes a cause and is therefore determined, no longer from without, but more and more from within himself.

The presentation of purely scientific issues is neither too technical for the general reader nor too simple for the professional. The author's advocacy of the expansion of the League of Nations from a judiciary to a legislature is more controversial. It merits, nevertheless, serious consideration, while there must be few who would refuse to endorse Lord Samuel's vigorous indictment of militarist philosophy. J. E. T.

The Physiological Basis of Medical Practice

a University of Toronto Text in Applied Physiology. By Prof. Charles Herbert Best and Prof. Norman Burke Taylor. Pp. xxi+1684. (London: Baillière, Tindall and Cox, 1937.) 45*s*.

MEDICINE and physiology owe much to one another and neither can advance far without the other. Many of the greatest physicians have been physiologists as well and have spent years of their lives on physiological problems, but of recent years, and particularly in Great Britain, a generation of physicians has grown up with no real training in scientific research.

A gap has no doubt formed between medicine and physiology, and the new book by Best and Taylor will help to fill it. The authors are both physiologists, and they believe that physiology is a science in its own right, but that it is the duty of those who teach it to medical students to emphasize those facts which are most clearly relevant to medical practice. The book covers the whole field of physiology with particular emphasis on human physiology, and without much physics or mathematics. In each section, the anatomy is discussed first, then the physiology, and then the applications in medicine. Pathological conditions such as nephritis, bronchiectasis, the leucæmias, Ménière's syndrome, syringomyelia and epilepsy are discussed from the physiological point of view. The discoveries of clinical science are more fully and sympathetically discussed than in previous volumes of this kind.

It might have been supposed that two authors who had set out to cover so wide a field would necessarily have acquired much of their information at third hand. The present book bears much evidence that its authors have not been content to put forward generally accepted conclusions without full consideration of the experimental evidence. The book is not a rehash of *Physiological Reviews*. In spite of much diligent reading, few errors have been noticed.

The chief defect of the book lies in the arrangement of the references, which are collected together at the end of the book, but grouped under chapters. Seekers after references must first discover what chapter they are reading, and then hunt through a lot of pages, many of which contain no indication of the number of the chapter to which they refer. J. H. G.

Gmelins Handbuch der anorganischen Chemie

Achte Auflage. Herausgegeben von der Deutschen Chemischen Gesellschaft. (1) System-Nummer 22: Kalium. Lief. 1: Element, Verbindungen bis Kalium und Sauerstoff. Pp. 246. 28.50 gold marks. (2) Lief. 2: Verbindungen bis Kalium and Chlor. Pp. 247–514. 3.50 gold marks. (Berlin: Verlag Chemie, G.m.b.H., 1936 and 1937.)

IN the volume on potassium considerable space is devoted to a discussion of the geological origin, distribution and character of the European potash deposits, with maps and a geological section reproduced from E. Fulda's book "Das Kali". The only compounds included in this part are those with hydrogen and oxygen.

The second part of the volume on potassium includes compounds containing the elements nitrogen, fluorine and chlorine. There is a general survey of the conditions which lead to the natural formation of potassium nitrate, the preparation of which from Chile saltpetre is relatively unimportant nowadays, since it has been largely replaced by other salts in the manufacture of explosives; but its properties are fully recorded. The peculiar behaviour of the system potassium fluoride – hydrogen fluoride is illustrated by a phase rule diagram which indicates the existence of no fewer than five complex compounds.

A very useful feature of this part is the compilation of references to the enormous mass of data about the physical properties of potassium chloride in the crystalline state and in aqueous solution. Thus numerous attempts have been made to link up the classical views of Arrhenius on electrolytic dissociation with the modern ideas of Debye. The technical production of this salt is being described in a later part. References to original memoirs and patent specifications relating to the manufacture of potassium chlorate by electrolysis of solutions of the chloride are very numerous. On the other hand, the electrolytic production of the perchlorate is rendered difficult by the low solubility of this salt, which leads to incrustation of the anodes, so that in practice it has generally to be made from the sodium salt.

Mathematische Methoden der Biologie:

insbesondere der Vererbungslehre und der Rassenforschung. Von Dr. Friedrich Ringleb. Pp. vii + 181. (Leipzig und Berlin: B. G. Teubner, 1937.) 8.80 gold marks.

THIS is essentially another text-book on elementary statistical methods written to assist scientific workers with a limited mathematical background to gain an understanding of the nature and usefulness of tools they are finding it necessary to use. A special group of workers is aimed at, as is indicated by the title; the plentiful illustrations are drawn from biological and botanical material and considerable space is given to the elementary algebraic description of the workings of Mendel's law and some of the simpler applications of the theory of probability to it.

The selection of topics is from definitely classical material, and it is to be hoped that readers of this book will also become acquainted with others at the same mathematical level which give an account of the present resources statistical methods offer. The exposition is good and the examples are clearly explained. Though sampling and correlation are treated in almost too brief and antiquated a fashion in view of the developments of the last twenty years, the author has done on the whole a good job within the limits of his material.

A few slips were noted. Thus we find it stated without qualification that $m(xy) = m(x)m(y)$ and that $\sigma^2(x+y) = \sigma^2(x) + \sigma^2(y)$. Hardy's summation method is attributed to H. Gunther. Class marks for distributions of continuous variables are incorrectly located, and the derivation of the Poisson law will confuse the student. CECIL C. CRAIG.

Transmutation of Matter

[Shortly before his death on October 19 last year, Lord Rutherford completed the presidential address which he proposed to deliver at the meeting of the Indian Science Congress Association on January 3–9. The latter part of the address is here reproduced and represents Lord Rutherford's last pronouncement on a subject with which his name will always be associated. Other matters discussed by him in the address were referred to in last week's leading article.—Editor, NATURE.]

TOWARDS the close of the nineteenth century, when it seemed certain that the atoms of the elements were unchangeable by the forces then at our command, a discovery was made which has revolutionized our conception of the nature and relations of the elements. I refer to the discovery in 1896 of the radioactivity of the two heaviest elements, uranium and thorium. It was soon made clear that this radioactivity is a sign that the atoms of these elements are undergoing spontaneous transmutation. At any moment, a small fraction of the atoms concerned become unstable and break up with explosive violence, hurling out either a charged atom of helium, known as an α-particle, or a swift electron of light mass called a β-particle. As a result of these explosions, a new radioactive element is formed, and the process of transmutation once started continues through a number of stages. Each of the radioactive elements formed in this way breaks up according to a simple universal law but at very different rates. In a surprisingly short time, these successive transformations were disentangled and more than thirty new types of elements brought to light, while the simple chemical relations between them were soon made clear.

We had thus been given a vision of a new and startling sub-atomic world where atoms break up spontaneously with an enormous release of energy quite uninfluenced by the most powerful agencies at our disposal. Apart from uranium and thorium and the elements derived from them, only a few other elements showed even a feeble trace of radioactivity. The great majority of our ordinary elements appeared to be permanently stable under ordinary conditions on our earth. Science was then faced with the problem whether artificial methods could be found to transmute the atoms of the ordinary elements. Before this problem could be attacked with any hope of success, it was necessary to know more of the actual constitution of atoms. This information was provided by the rise of the nuclear theory of atomic structure, which I first suggested in 1911 The essential controlling feature of all atoms was found to reside in a very minute central nucleus which carried a positive charge and contained most of the mass of the atom. A relation of unexpected simplicity was found to connect the atoms of all the elements. The ordinary properties of an atom are defined by a whole number, which represents the number of units of resultant positive charge carried by the nucleus. This varies from 1 for hydrogen to 92 for the heaviest element uranium, and, with few exceptions, all the intervening numbers correspond to known elements.

On this view of atomic structure it was evident that, to bring about the transmutation of an atom, it was necessary in some way to alter the charge or mass of the nucleus or both together. Since the nucleus of an atom must be held together by very powerful forces of some kind, this could only be effected by bringing a concentrated source of energy of some kind to bear on the individual nucleus The most energetic projectile available at that time was the swift α-particle spontaneously ejected from radioactive substances. If a large number of α-particles were fired at random at a sheet of matter, it was to be expected that one of them must occasionally approach very closely to the nucleus of any light atom in its path. In such a close encounter, the nucleus must be violently disturbed, and possibly under favourable conditions the α-particle might actually enter the nuclear structure.

This mode of attack upon the nucleus at once proved successful. I found in 1919 that nitrogen could be transformed by bombardment with fast α-particles. The process of transmutation is now clear. Occasionally an α-particle actually enters the nitrogen nucleus and forms with it a new unstable nucleus which instantly breaks up with the emission of a fast proton (hydrogen nucleus) and the formation of a stable isotope of oxygen of mass 17. About a dozen of the light elements were found to be transformed in a similar way. The protons liberated in the nuclear explosions were at first counted by observing the flashes of light (scintillations) produced in phosphorescent zinc sulphide. This method was slow and very trying to the eyes of the observers. Progress, however, became more rapid and definite when electrical methods of counting individual fast particles were developed. These electrical counters, mainly depending on the use of electron tubes for magnifying small currents, have now reached such a stage of perfection that we are able to count automatically individual fast particles like α-particles and protons even though they enter the detecting chamber at a rate as fast as ten thousand per minute. By other special devices, we are in like manner able to count individual β-particles. In this connexion, I must not omit to mention that wonderful instrument, the Wilson expansion chamber, which makes visible to us the actual tracks of flying fragments of atoms resulting from an atomic explosion. These remarkable devices have played an indispensable part in the rapid growth of knowledge during the last few years. It is to be emphasized that progress in scientific discovery is greatly influenced by the development of new technical methods and of new devices for measurement. With the growing complexity of science, the development of special techniques is of ever-increasing importance for the advance of knowledge.

Up to the year 1932, experiments on transmutation were confined to the use of α-particles for bombarding purposes. It became clear that the process of transformation was in most cases complex, since groups of protons with different but characteristic energies were observed when a single element was bombarded. This led to the conception that discrete energy levels existed within a nucleus, and that under some conditions part of the excess energy was sometimes released in the form of a quantum of high-frequency radiation.

The stage was now set for a great advance, and four new discoveries of outstanding importance were made in rapid succession in the period 1931–33. I refer to the discovery of the positive electron by Anderson in 1931, of the neutron by Chadwick in 1932, of artificial radioactivity by M. and Mme. Curie-Joliot in 1933 and of the transmutation of the elements by purely artificial methods first shown by Cockcroft and Walton in 1932.

The discovery of the neutron—that uncharged particle of mass nearly 1—was the result of a close study of the effects produced in the light element beryllium when bombarded by α-particles. It is noteworthy that the proton and neutron, which are now believed to be the essential units with which all atomic nuclei are built up, owe their recognition to a study of the transmutation of matter by α-particles.

Before the discovery of the neutron, it had been perforce assumed that nuclei must in some way be built up of massive protons and light negative electrons. Theories of nuclear structure became much more amenable to calculation when the nucleus was considered to be an aggregate of parts like the proton and neutron which have nearly the same mass. There was no longer any need to assume that either the positive or the negative electron has an independent existence in the nuclear structure. We are still uncertain of the exact relation, if any, between the neutron and the proton. The neutron appears to be slightly more massive than the proton, but it is generally believed, although no definite proof is available, that the proton and neutron within a nucleus are mutually convertible under certain conditions. For example, the change of a proton into a neutron within the nucleus should lead to the appearance of a free positive electron, while conversely the change of a neutron into a proton gives rise to a free negative electron. In this way it appears possible to account for the observed fact that either positive or negative electrons are emitted by a large group of radioactive elements to which I will now refer.

In the early experiments on transmutation by α-particles, it was supposed that a stable nucleus was always formed after the emission of a fast proton. The investigations of M. and Mme. Curie-Joliot showed that in some cases elements were formed which, while momentarily stable, ultimately broke up slowly, exactly like the natural radioactive bodies. Most of these radioactive bodies formed by artificial methods break up with the expulsion of fast negative electrons, but in a few cases positive electrons are emitted. Since the presence of these radioactive bodies can be easily detected, and their chemical properties readily determined, this new method of attack on the problem of transmutation has proved of great value. Nearly a hundred of these radioactive bodies are now known, produced in a great variety of ways. Some arise from the bombardment by fast α-particles, others by bombardment with protons or deuterons. As Fermi and his colleagues have shown, neutrons, and particularly slow neutrons, are extraordinarily effective in the formation of such radioactive bodies. On account of its absence of charge, the neutron enters freely into the nuclear structure of even the heaviest element, and in many cases causes its transmutation. For example, a number of these radioactive bodies are produced when the two heaviest elements, uranium and thorium, are bombarded by slow neutrons. In the case of uranium, as Hahn and Meitner have shown, the radioactive bodies so formed break up in a succession of stages like the natural radioactive bodies, and give rise to a number of trans-uranic elements of higher atomic number than uranium (92). These radioactive elements have the chemical properties to be expected from the higher homologues of rhenium, osmium and iridium of atomic numbers 93, 94 and 95.

These artificial radioactive bodies in general represent unstable varieties of the isotopes of known elements which have a limited life. No doubt such transient radioactive elements are still produced by transmutation in the furnace of our sun, where the thermal motions of the atoms must be very great. These radioactive elements would rapidly disappear as soon as the earth cooled down after separation from the sun. On this view, uranium and thorium are to be regarded as practically the sole survivors in our earth of a large group of radioactive elements, owing to the fact that their time of transformation is long compared with the age of our planet.

It is of interest to note what an important part the α-particle, which is itself a product of transformation of the natural radioactive bodies, has played in the growth of our knowledge of artificial transmutation. It is to be remembered, too, that our main source of neutrons for experimental purposes is provided by the bombardment of beryllium with α-particles. The amount of radium available in our laboratories is, however, limited, and it was early recognized that if our knowledge of transmutation was to be extended, it was necessary to have a copious supply of fast particles of all kinds for bombarding purposes. It is well known that enormous numbers of protons and deuterons, for example, can be easily produced by the passage of the electric discharge through hydrogen and deuterium (heavy hydrogen). To be effective for transmutation purposes, however, these charged particles must be given a high speed by accelerating them in a strong electric field. This has involved the use of apparatus on an engineering scale to provide voltages as high as one million volts or more, and the use of fast pumps to maintain a good vacuum.

A large amount of difficult technical work has been necessary to produce such high D.C. voltages and to find the best methods of applying them to the accelerating system. In Cambridge, these high voltages are produced by multiplying the voltage of a transformer by a system of condensers and rectifiers; in the United States of America by the use of a novel type of electrostatic generator, first developed by van der Graaf. Prof. Lawrence, of the University of California, has devised an ingenious instrument called a 'cyclotron' in which the charged particles are automatically accelerated in multiple stages. This involves the use of huge electromagnets and very powerful electric oscillators. By this method he has succeeded in producing streams of fast particles which have energies as high as the α-particle ejected from radioactive substances. Undoubtedly this type of apparatus will prove of great importance in giving us a supply of much faster particles than we can hope to produce by the more direct methods.

It was at first thought that very high potentials of the order of several million volts would be required to obtain particles to study the transmutation of elements. Here, however, the development of the theory of wave-mechanics came to the aid of the experimenter, for Gamow showed that there was a small chance that comparatively slow bombarding particles might enter a nucleus. This theoretical conclusion has been completely verified by experiment. In the case of a light element like lithium, transformation effects can be readily observed with protons of energy as low as 20,000 volts. Of course, the amount of transformation increases rapidly with rise of voltage.

The study of the transmutation of elements by using accelerated protons and deuterons as bombarding particles has given us a wealth of new information. The capture of the proton or deuteron by a nucleus leads in many cases to types of transmutation of unusual interest. For example, the bombardment of the isotope of lithium of mass 7 by protons leads to the formation of a beryllium nucleus of mass 8 with a great excess of energy. This immediately breaks up into two α-particles shot out in nearly opposite directions. When boron 11 is bombarded by protons, a carbon nucleus of mass 12 is formed which breaks up in most cases into three α-particles. The deuteron is in some respects even more effective than the proton as a transmuting agent. When deuterons are used to bombard a compound of deuterium, previously unknown isotopes of hydrogen and of helium of mass 3 are formed, while fast protons and neutrons are liberated. The bombardment of beryllium by very fast deuterons gives rise to a plentiful supply of neutrons. Lawrence has shown that the bombardment of bismuth by very fast deuterons leads to the production of a radioactive bismuth isotope which is identical with the well-known natural radioactive product radium E. Many artificial radioactive elements can be produced, often in great intensity. For example, the bombardment of common salt by fast deuterons gives rise to a radioactive isotope of sodium. This breaks up with a half period of 15 hours, emitting not only fast β-particles but also γ-rays at least as penetrating as those from radium.

It may well be that in course of time such artificial radioactive elements may prove a useful substitute for radium in therapeutic work. By these methods also, such intense sources of neutrons can be produced that special precautions have to be taken for the safety of the operators of the apparatus.

Sufficient I think has been said to illustrate the variety and interest of the transmutations produced by these bombardment methods. It should, however, be pointed out that transmutation in some cases can be effected by transferring energy to a nucleus by means of γ-rays of high quantum energy instead of by a material particle. For example, the deuteron can be broken up into its components, the proton and neutron, by the action of the γ-rays from radium or thorium. As a result of the bombardment of lithium by protons, γ-rays of extraordinarily great quantum energy as high as 17 million volts are strongly emitted. Bothe has recently shown that these high-energy rays are able to transmute a number of atoms, neutrons usually being emitted in the process.

Some simple laws appear to hold in all individual transformations so far examined. Nuclear charge is always conserved, and where heavy particles are emitted, so also is energy when account is taken of the equivalence of mass and energy. Certain difficulties arise with regard to the conservation of energy in cases where light positive and negative electrons are emitted during transmutation, and there is still much discussion on this important question.

The study of the transmutation of matter has been extraordinarily fruitful in results of fundamental importance. In addition to the α-particle, it has disclosed to us the existence of those two building units of nuclei, the proton and neutron. It has greatly widened our conception of the varieties of atomic nuclei which can exist in Nature. Not only has it led to the discovery of about one hundred new radioactive elements, but also of several stable isotopes of known elements, like ^{3}H, ^{3}He, ^{8}Be, which had previously been unsuspected. It has greatly extended our knowledge of the ways in which nuclei can be built up and broken down, and has brought to our attention the extraordinary violence of some of the nuclear explosions which occur. The great majority of our elements have been transmuted by the bombardment method, and in the case of the light elements which have been most carefully studied, a great variety of modes of transmutation has been established.

Rapid progress has been made, but much still remains to be done before we can hope to understand the detailed structure and stability of different forms of atomic nuclei and the origin of the elements. I cannot but reflect on the amazing contrast between my first experiment on the transmutation of nitrogen in the University of Manchester in 1919 and the large-scale experiments on transmutation which are now in progress in many parts of the world. In the one case, imagine an observer in a dark room with very simple apparatus painfully counting with a microscope a few faint scintillations originating from the bombardment of nitrogen by a source of α-particles. Contrast this with the large-scale apparatus now in use for experiments on transmutation in Cambridge. A great hall contains massive and elaborate machinery, rising tier on tier, to give a steady potential of about two million volts. Nearby is the tall accelerating column with a power station on top, protected by great corona shields—reminding one of a photograph in the film of Wells's "The Shape of Things to Come". The intense stream of accelerated particles falls on the target in the room below, with thick walls to protect the workers from stray radiation. Here is a band of investigators using complicated electrical devices for counting automatically the multitude of fast particles arising from the transformation of the target element, or photographing with an expansion chamber, automatically controlled, the actual tracks of particles from exploding atoms.

To examine the effect of still faster particles, a cyclotron is installed in another large room. The large electromagnet and accessories are surrounded with great water tanks containing boron in solution to protect the workers from the effect of neutrons released in the apparatus. A power station nearby is needed to provide current to excite the electromagnet and the powerful electric oscillators.

Such a comparison illustrates the remarkable changes in the scale of research that have taken place in certain branches of pure science within the last twenty years. Such a development is inevitable, for, as science progresses, important problems arise which can only be solved by the use of large powers and complicated apparatus, requiring the attention of a team of research workers. If rapid progress is to be made, such team work is likely to be a feature of the more elaborate researches in the future. Fortunately there is still plenty of scope for the individual research worker in many experiments of a simpler kind.

The science of physics now covers such a vast field that it is impossible for any laboratory to provide up-to-date facilities for research in more than a few of its branches. There is a growing tendency in our research laboratories to-day to specialize in those particular branches of physics in which they are most interested or specially equipped. Such a division of the field of research amongst a number of universities has certain advantages, provided that this subdivision is not carried too far. In general, the universities should be left free so far as possible to develop their own lines of research and encouraged to train young investigators, for it cannot be doubted that vigorous schools of research in pure science are vital to any nation if it wishes to develop effectively the application of science, whether to agriculture, industry or medicine. Since investigations in modern science are sometimes costly, and often require the use of expensive apparatus and large-scale collaboration, it is obviously essential that adequate funds should be available to the universities to cover the cost of such researches.

Progress in Chemotherapy

PEOPLE in settled and civilized countries, such as Great Britain, are familiar with the beneficent results of the application of the methods of preventive medicine, but these methods are not easy to apply among primitive populations, and in the tropical parts of the Empire the effects of preventive methods are apt to be much less apparent than those brought about by curative medicine, making use of the products of chemotherapeutical investigation, in the treatment of endemic plagues such as malaria, sleeping sickness, bilharzia, hookworm disease and kala-azar. It is fitting that the value of such work should be recognized, and the decision of His Majesty's Government to spend £30,000 per annum in promoting chemotherapeutical investigations is a welcome move in the right direction. Although work of this kind has not so far been undertaken in Great Britain on so large a scale as in some Continental countries, the amount done is by no means negligible, as was evident from the partial survey of recent work made in the course of a discussion on "The Influence of Structure on the Action of Parasiticidal Drugs" held under the auspices of the Chemical Society on Thursday December 2, in which both biologists and chemists took part.

In his opening remarks, Dr. T. A. Henry suggested that such investigations are usually conducted in one of two ways. The method by which most of the practical successes of chemotherapy have been achieved depends upon the discovery of a clue in the form of a drug to which the pathogenic organism associated with a disease is more or less vulnerable. The course of such an investigation was illustrated by a brief account of work on kala-azar, which, starting with the observation in 1915 that this disease could be successfully treated by tartar emetic, resulted in the replacement of that unpleasant drug by derivatives of *p*-aminophenylstibonic acid, made possible by Dr. Hans Schmidt's discovery in 1911 of a method of preparing arylstibonic acids[1]. The second method depends upon the idea that toxicity to a range of parasites may be associated with a particular type of chemical structure, and that pharmacological investigation of a series of drugs in which the structural type is maintained may afford useful information as to the mode of action of such drugs—a difficult subject upon which there has been much speculation, but little real progress. At present such investigations are in progress on the influence of chemical modification on the action of cinchona alkaloids in bird malaria and auricular fibrillation[2] and on their pneumococcicidal activity[3]. It has been found that modification of the vinyl side-chain in quinine and quinidine makes little difference to anti-malarial action, but that any interference with the central –CHOH– group reduces or extinguishes activity, even when there is only a change in spatial distribution, as in the conversion of quinine into Rabe's *epi*–C^9–quinine. In a homologous series of *apo*quinine or dihydrocupreine alkyl ethers, anti-malarial action does not rise to a maximum and then fall as the series is ascended, but shows this behaviour in an alternating form, the members with odd and even numbers of carbon atoms forming two sub-series, each giving an independent maximum.

Discussing the biological side of such investigations, Dr. J. W. Trevan said that even when allowance is made for the crudity of the pharmacological methods available and the variability of the test object, there is no doubt that small structural changes do profoundly modify the pharmacological action of many substances, which is not surprising in view of the narrow limits of tolerance for environmental change shown by living cells. Mere methylation of an amino-group may reduce the anæsthetic action of a compound by reducing the concentration of base free at the hydrogen ion concentration of the body. The difference in effect between the chains of odd and even numbers of carbon atoms referred to by Dr. Henry may be due to differences in spatial arrangement. Müller has shown that the normal paraffins have the carbon atoms arranged in a zig-zag form. It is not unlikely that these drugs act on a surface film of the cell composed of protein, possibly containing some such substance as cholesterol, possessing a recurrent pattern. If the drug is anchored by the characteristic group of the alkaloid and the plane of the zig-zag is at right angles to the surface with its axis parallel with the surface, the distance of the terminal methyl group will not be the same for the odd and even numbered chain, and it would be interesting to construct a model of the molecule and to determine whether such an explanation is feasible

Prof. F. L. Pyman summarized briefly the results of his work on *n*-alkylphenols and on amœbicides, of which an account has been published recently in NATURE (140, 409, 832; 1937). The results are of special interest as showing that amœbicidal action *in vitro* is exhibited by compounds wholly different in structure from emetine, the most active substance found being $\alpha\ \varkappa$-tetra-*n*-amyldiamino-*n*-decane, which, however, proved not to be of clinical value.

Sir Gilbert Morgan then gave an account of work done on homologous series of derivatives of *p*-aminophenylarsonic acids of the general formula $(HO)_2.AsO.C_6H_4.NH.CO(CH_2)_n.CO.NR_1R_2$, which may be regarded as combining the desirable features of the well-known arsenical drugs, acetyl-*p*-arsanilic acid and tryparsone, $(NaO)(OH).AsO\ C_6H_4.NH.CH_2.CONH_2$, the latter being probably the most widely used drug of this type for the treatment of sleeping sickness and late syphilis. Among the new drugs, sodium succinanilomethylamide-*p*-arsonate ($n = 2$; $R_1 = H$; $R_2 = CH_3$) has been selected and has already given promising results in clinical trials in sleeping sickness in Nigeria. In connexion with the same investigation, Dr. E. Walton directed attention to the low toxicity of this type of arsenical compound, and showed that trypanocidal action is enhanced by an amide-group in the *p*-position in phenylarsonic acid[4].

The next two contributions dealt with the new streptococcicidal drugs, of which the first example was Domagk's 2 : 4-diaminoazobenzene-4′-sulphonamide[5], which was speedily shown, as the result of work in France and in Great Britain, to be replaceable by the simpler substance *p*-aminobenzenesulphonamide (sulphanilamide), which is already in use on a large scale. Mr. W. H. Gray stated that the results of numerous attempts to improve upon this simple substance indicated that both the sulphur atom and the amino-group are essential, that duplication of either on the same nucleus destroys activity, which is also the effect of additional substituents. A more active but more toxic substance is 4 : 4′-diaminodiphenylsulphone, in which activity also disappears on elimination of either the sulphone or the amino-groups. Dealing with biological work on these drugs, Dr. G. A. H. Buttle said that sulphanilamide will cure mice infected with 10,000 times the lethal dose of streptococci. As tested on mice, the drug appears to have some action in all bacterial infections characterized by rapid multiplication of the invading bacterium, but it fails in infections where a small number of organisms can produce a sufficiently potent toxin to kill the animal, as in diphtheria. As regards the mode of action, there is experimental evidence for the view that by some means still unknown the drug delays the growth of the organisms or affects them in such a manner as to facilitate their destruction by the leucocytes of the blood[6].

Returning to anti-malarial drugs, Dr. H. King described work done in collaboration with Dr. Cohen and Dr. Ainley on two substances based on the structure of quinine, details of which will be published shortly.

Dr. W. H. Linnell showed that although there are a number of useful acridine derivatives in use in medicine as bactericides and amœbicides, the possibilities of this heterocyclic nucleus have not been fully explored, and in his recent survey[7] of monoamino- and diamino-acridines, he has found that 1-aminoacridines are not bactericidal, that an amino-group in position 3 lowers toxicity and that 3 : 8-diaminoacridine is as active as, but much less toxic than, the well-known 2 : 8-diaminoacridine (proflavine).

The Quatercentenary of the University of Coimbra

THE beautiful old city of Coimbra, the ancient capital of the kingdom of Portugal from the time of King Afonso Henriques to that of King Afonso III, rises picturesquely from the banks of the Mondego River and is crowned by the historic buildings of its university. The first centre of higher learning in Portugal, the first "Estudo geral", was established at Lisbon in March 1290 by King Diniz, but was later brought to the capital at Coimbra (in 1308). Twice transferred back in the fourteenth century (1338 and 1377) to the banks of the Tagus, the University was finally established at Coimbra in 1537 by King John III, who had undertaken a great reform of university studies. These reforms culminated in the reign of King José I, when in the last quarter of the eighteenth century his famous Prime Minister, the Marquês de Pombal, greatly transformed and modernized the work of the University, introducing especially the study of natural science.

The four hundredth anniversary of the final establishment of the University at Coimbra in 1537 was celebrated during the days December 6–10 by a series of fine ceremonies and much splendid hospitality. Many men of letters and science had come from various parts of the world to do honour to the famous University, and were entertained in a most lavish manner by the Government of Portugal, the University authorities, and the City of Coimbra.

The British guests who had come specially to Portugal for the quatercentenary were Prof. F. G. Donnan (chemistry, University of London and the Royal Society) and Miss Jane Donnan, Prof. W. J. Entwistle (Spanish and Portuguese, University of Oxford), Mr. J. Ramsbottom (keeper of botany, British Museum (Natural History)), Prof. W. F. Starkie (Spanish and Italian, Trinity College, Dublin) and Prof. W. M. Thornton (electrical engineering, Universities of Durham, Birmingham, Reading and Bristol). The British Embassy in Lisbon was represented by the chargé d'affaires, Mr. Bateman, and the secretary, Mr. Gorell-Barnes (who also represented the University of Cambridge), whilst Mr. Dible, British Consul in Oporto, represented the consular service. Notable amongst those who represented the British colony in Lisbon were Mr. R. G. Jayne, head of the well-known shipping firm of Garland, Laidley and Co., and the Rev. Stewart Robertson (who also represented the University of Edinburgh) and Mrs. Robertson.

The celebrations began in the afternoon of December 6 with a general assembly in the "Patio" of the University, followed by addresses of welcome and a reception in the splendid official apartments of the distinguished Rector of the University, Dr. João Duarte de Oliveira.

During the forenoon of December 7 an exhibition of books was opened in the general Library of the University. This building, constructed between 1717 and 1725 on the initiative of the Rector, Nuno da Silva Teles, is a magnificent example of the Portuguese baroque style of the period of King John V, and contains a vast store of valuable manuscripts and books. There was also opened at the same time a most interesting display of early documents in the archives of the University.

At noon came addresses of welcome by the City Council and a reception in the University; the President of the Republic, his Excellency General Oscar de Fragoso Carmona, had intended to be present, but he was prevented from doing so by indisposition.

Most of the afternoon of December 7 was dedicated to a solemn session in the famous "Sala dos Capêlos" of the University. This noble hall was the work of the Rector, Manuel de Saldanha, who in 1654 decided to transform and embellish the great salon of the Royal Palace which at that time served for the ceremonies of the University. It possesses a fine dado of the beautiful "azulejos", that is, painted and glazed tiles, for which Portugal is so famous, and a splendid domed ceiling of painted panels, whilst its walls are adorned by portraits of the kings and queens of Portugal. Addresses were delivered by the Rector and the Minister of Education, Dr. Antonio Faria Carneiro Pacheco, and Prof. Damião Peres gave an eloquent account of the University of Coimbra in the history of Portuguese culture. Then short speeches of congratulation were made by members of the various foreign delegations, Prof. Entwistle speaking in Portuguese on behalf of the representatives of Great Britain

The afternoon of December 7 concluded with the inauguration of the "Sala do Brasil" in the Faculty of Letters. In the evening a splendid gala dinner was given in the University, at which were present the diplomatic corps and the senior delegates of the various nations. This was followed by a concert given by the symphony orchestra of the national broadcasting station. The Prime Minister, his Excellency Dr. Antonio de Oliveira Salazar, was able to be present during a part of these festivities.

At 11 o'clock on the morning of December 8, High Mass was celebrated by his Eminence the Cardinal Patriarch of Portugal, whilst during the afternoon in the Sala dos Capêlos, Senhor Mario Brandão was admitted to the degree of doctor, and honorary doctorates were conferred on a number of the foreign delegates, including Prof. Donnan and Mr. Ramsbottom. This was a scene never to be forgotten by the visitors. Round the great hall sat the diplomatic corps and the professors of the various faculties, the latter clad in their black gowns and silken "capelos" (differing in colour for each faculty) and wearing on their heads the wonderful "borlas" or academic hats. The body of the hall was filled with many ladies and guests of the University, whilst at the back surged an enthusiastic throng of students who gave Dr. Brandão and the honorary doctors a very hearty welcome. An extremely interesting feature of this ancient and historic ceremony was the embracing of the Rector Magnificus and the dean of the faculty by each honorary doctor in turn, whilst Dr. Brandão had the further privilege of being led round the stalls and the duty of embracing all the members of the faculties. One realized that this was a noble ceremony characteristic of the ancient brotherhood of learning, in which every new doctor was admitted to a special order and given a very friendly welcome by his elder brothers.

In the evening of December 8 a great banquet was given by the City Council in the hall of the splendid new High School named after King John III. At this banquet many students, all clad in their characteristic long black gowns, were present, so the proceedings were much enlivened by the gaiety and joy of youth. Various foreign delegates (including the present writer) were haled from the high table by groups of very pleasant fellows, given a student's gown, and conducted round the hall amidst cheers and rejoicing. One signed innumerable cards, drank much of the good wine of the country to the honour of Coimbra and Portugal, tried to speak bad Portuguese, and endeavoured to keep one's head and feet. It was evident that these good fellows, the representatives that night of the hope of the world, were admitting us to their comradeship and to the fellowship of the University of Coimbra. May God bless them!

On December 9 the programme included a football match and a torchlight procession of the students. Unfortunately, these events had to be cancelled owing to heavy rain. However, there was a very interesting concert of Portuguese music in the afternoon, given by the Philharmonic Orchestra of Lisbon, an evening meeting in the Avenida Theatre, and a gala ball in the great High School of King John III.

The celebrations closed on December 10 with a visit to the beautiful mountain resort of Buçaco and a lunch in the Palace Hotel. Thus terminated a visit to Coimbra and its famous University which will live in the memories of the British delegates as one of the pleasantest and most interesting events of their lives. The old city of Coimbra, crowned by its ancient University, and with its great Romanesque Cathedral of Sé Velha and its old church of Santa Cruz, in which lie buried King Afonso Henriques and King Sancho I, will ever remain with us a vivid and happy memory. We retain also a keen appreciation of the present as well as of the glorious past, and rejoice to have seen with our own eyes the great advances made in the University of Coimbra, as elsewhere in the land of our ancient and loyal allies, under the wise and beneficent leadership of President General Carmona and his great Prime Minister, Dr. Salazar. Dr. Salazar himself is a man of learning, one of the greatest, if not the greatest, of the sons of his Alma Mater, Coimbra. A distinguished professor of that University, destiny has led him to dedicate his pre-eminent abilities and virtues to the prosperity and happiness of the land of his birth. We who have experienced the splendid hospitality of his Government, and have had the privilege of witnessing the great and beneficent results of his wise and patriotic leadership of the Portuguese nation, unite wholeheartedly in wishing him and all our good friends of Portugal every prosperity and happiness in the future.

Before leaving Coimbra, I spent a very pleasant afternoon in the company of the professors of chemistry, Prof. Ruy Gustavo Couceiro da Costa and Prof. K. Coper. A remarkable experience was the visit to the Chemical Laboratory, a building in the neo-classical style erected in the last quarter of the eighteenth century during the reform period of the Marquês de Pombal (who approved and signed the architect's plan). How it would have rejoiced the heart of Lavoisier! Certainly the great Marquis must have been a man of remarkable foresight, and one cannot blame him or his architect for not having designed a building suitable to the requirements of 1937. Various interesting researches were in progress—a proof that good work can be done in buildings of great historical interest. Nevertheless, in case these lines should meet the eyes of Dr. Salazar—which is, perhaps, unlikely—I would humbly suggest that now is the time for him to beat the record of the great Marquis!

Another very interesting visit was paid to the English Institute, due to the energy and initiative of Dr. West, and now under the able direction of Mr. Leonard S. Downes, who represented the University of Glasgow at the celebrations. Amongst many other things, one was astonished to find here a library containing some English scientific journals and a goodly number of the most modern English books on chemistry and physics. In fact, the professors of chemistry told me that they were much indebted to the English Institute for keeping them in touch with the progress of British science. It is evident that the English Institute is very much alive and worthy of the strongest support. In the modern world the 'invisible' export of thought is an element of deep significance and importance. Britons in the past have been too apt to think that foreign nations are bound to assimilate the products of their thought and research by reason of some sort of inevitable predestination. This curious diffidence—or sublime trust in Providence—is not much good in the rough catch-as-catch-can of the thrusting modern world.

So, at last, came the train that bore us away from this city of learning, poetry and romance, where immortal Camões once lived and beautiful Inéz de Castro loved and suffered. With every student of Coimbra one could exclaim, "Não é Universidade como a minha!"

In conclusion, the British visitors to the Coimbra quatercentenary are deeply indebted to His Majesty's Embassy at Lisbon for invaluable help and much personal care and attention. Several of us, including the writer of this article, desire also to express our grateful thanks to Mr. Pell, the Minister of the United States in Portugal, and Mrs. Pell, for very delightful hospitality.

F. G. Donnan.

Obituary Notices

Prof. Charles Gravier

PROF. CHARLES GRAVIER, of the Natural History Museum of Paris, died on November 15 in his seventy-third year. Born at Orléans in 1865, and educated at the Ecole Normale of Saint-Cloud, he made his first step in the academic service of his country with an appointment in 1887 to a professorship at the Ecole Normale of Grenoble. In 1893, he was *agrégé des Sciences Naturelles* and in 1894 became *Professeur de Lycée* at Clermont-Ferrand, and two years later obtained his doctorate with a thesis on the Polychæta entitled "Recherches sur les Phyllodociens".

From Clermont-Ferrand Gravier moved to Paris, where he held the post of assistant first to E. Perrier and afterwards to L. Joubin at the Natural History Museum. In 1917 he was appointed *Professeur au Muséum* (*Vers et Crustacés*), a chair which he held until his death, and in 1922 he was elected a member of the Paris Academy of Sciences. He married a lady who also belonged to the academic world, for she held a chair of mathematics at the Ecole Normale of Sèvres, and their only son Maurice is a student of Scandinavian and Germanic philology.

Gravier saw more of the world than most men that follow an academic career, for he worked at the Zoological Station at Naples, at Bergen, in Germany, and was familiar with all the principal European museums. He went twice to America, and was entrusted with two scientific missions, to San Thomé in the Gulf of Guinea and afterwards to Djibouti in the Red Sea.

Gravier's life was devoted to the study of marine zoology, and his great powers of work enabled him to cover a wide field. He was mainly preoccupied with the systematics and morphology of the Polychæta and the Cœlenterates, but he was also deeply interested in their bionomics, and he had the capacity of extracting the last ounce of evolutionary significance from his material. He wrote upwards of eighty papers on the Cœlenterates, dealing with nearly all the groups of that phylum, and about a hundred and thirty papers on the Polychæta, of which nearly thirty were in collaboration with J. L. Dantan. He also published on the Crustacea and sponges.

Much of Gravier's work was in the form of short notes, two or three pages in length, but he also contributed a number of substantial memoirs. For example, in the Cœlenterates he described the corals of the second French Antarctic expedition and also those collected by the Prince of Monaco's oceanographic expeditions. In the Crustacea he described in 1912 the parasitic Copepoda of the second French Antarctic expedition and in 1931 published a valuable account of the breeding habits of the group. The bulk of his work was on the Polychæta, and in this group his main contributions were the description of the Polychæta of the first and second French Antarctic expeditions, his memoir on the Polychæta of the Red Sea, his papers on the breeding habits of the group, and more recently his account in collaboration with J. L. Dantan of the planktonic Polychætes obtained by fishing at night with a light in the Bay of Algiers and off the coast of Annam. He also made a special study of freshwater Polychætes.

All Gravier's work was careful and finished, and displayed the characteristic French clarity, proportion and sense of style. As a man, he had great charm. He never obtruded his great learning and always remained courteous, unassuming and kind,

C. C. A. M.

Prof. E. L. Nichols

ON November 10 the death occurred of Prof. E. L. Nichols, emeritus professor of physics in Cornell University, in his eighty-fourth year. Prof. Nichols's connexion with Cornell was of very long standing, as he studied there from 1871 until 1875 and was appointed professor of physics in the University in 1887. Thus for the past fifty years he has been continuously associated with Cornell, his appointment as emeritus professor dating from 1919. Previous to 1887, he had held the post of professor of physics, first at the University of Kentucky and then at Kansas University.

The period through which Prof. Nichols lived was one of most active and intense development in the realm of physics; this will be the more readily appreciated from the fact that he was for a short time associated with Edison in the development of the incandescent lamp. Throughout his life, his most constant interest was in photometry, optics and fluorescence, and he was responsible for a very large number of papers on various aspects of these subjects. His investigations of fluorescent phenomena were particularly numerous, and the book he wrote in collaboration with H. L. Howes and D. T. Wilbur on "Cathodo-Luminescence and the Luminescence of Incandescent Solids" is probably his most important work. Measurements of fluorescence are difficult at any time, and in his early work Prof. Nichols must have been very seriously hampered by the absence of the photometric standards to which we are now accustomed; but it must have been a source of considerable interest and satisfaction to him to see the rapidly growing industrial importance of the subject of fluorescence during the last few years, in connexion with new forms of lighting devices and with cathode ray tube development.

In addition to his own research activities, Prof. Nichols played an important part at the end of the last century in placing research in its correct perspective in American universities. At that time, teaching was almost the sole concern of the staffs of the various universities, and it is largely due to the energy and foresight of men such as him that at the present time the majority of American universities recognize research as being one of their most important functions.

In 1929, Prof. Nichols was awarded the Ives Medal of the Optical Society of America, and the present writer recollects with pleasure the dinner at which the medal was presented, and the speech by the late Mr. I. G. Priest, then president of the Society, in which he referred in glowing terms to the great service the medallist had rendered to optics.

W. D. W.

THE death is reported from Wellington, New Zealand, of Dr. Herbert William Williams, Bishop of Waiapu and well known as a Maori scholar, which took place on December 7 at the age of seventy-seven years. Dr. Williams was the third in descent of his family to hold this bishopric, both his grandfather and his father having held it before him. Dr. Williams was born at Waeranga-a-hika and was educated at Christ's College, Christchurch, and Canterbury College. After graduating in the University of New Zealand, he held a scholarship at Jesus College, Cambridge, where he graduated as a senior optime in 1884. After a brief period as a master at Haileybury he was ordained. In 1888 he returned to New Zealand, and in 1929 was elected to succeed Bishop Sedgwich in this diocese. Dr. Williams's life-long acquaintance and friendship with the Maori gave him an exceptional position as an authority on their history and culture. He was the author of a Maori dictionary, which appeared in 1917, of a bibliography of printed Maori, which appeared in 1924, and of "First Lessons in Maori". His scholarship was recognized by the award of the degree of Litt.D. of the University of New Zealand in 1924 and of the Litt.D. of Cambridge in 1925. He was a fellow of the Royal Society of New Zealand, of which he was president in 1935. He was also president of the Polynesian Society in 1929.

WE regret to announce the following deaths :

Prof. G. A. Buckmaster, emeritus professor of physiology in the University of Bristol, on December 19, aged seventy-eight years.

Mr. A. G. Edie, C.I.E., formerly chief conservator of forests, Bombay, on December 18, aged sixty-five years.

Prof. L. N. G. Filon, C.B.E., F.R.S., Goldsmid professor of mathematics in the University of London, formerly vice-chancellor of the University, on December 29, aged sixty-two years.

Miss Elizabeth Sanderson Haldane, C.H., author of works on Descartes, Ferrier and Hegel, and known for her interest in adult education, on December 24, aged seventy-five years.

Rear-Admiral R. S. Patton, since 1929 director of the U.S. Coast and Geodetic Survey, on November 25, aged fifty-four years.

Dr. Ivan K. Urumoff, known for his work on the flora of Bulgaria, aged eighty-one years.

News and Views

New Year Honours

THE New Year Honours list contains the names of the following men of science and others associated with scientific work : *Viscount* : Lord Nuffield, for public and philanthropic services. *Baron* : Sir Henry Lopes, Bt., deputy president of the University College of the South West, Exeter. *G.C.V.O.* : Lord Horder. *G.B.E.* : Sir Andrew Duncan, chairman of the Central Electricity Board, 1927–35. *K.C.B.* : Mr. K. McK. Clark, director of the National Gallery and surveyor of the King's Pictures. *K.B.E.* : Mr. T. Rigg, director of the Cawthron Institute, Nelson, Dominion of New Zealand ; Dr. W. H. McLean, for services to education and economic development in the Colonies ; Dr. W. D. Ross, president of the British Academy and provost of Oriel College, Oxford. *Knights* : Dr. Zia-Uddin Ahmad, vice-chancellor of the Aligarh Muslim University, United Provinces, India ; Prof. G. A. R. Callender, first director of the National Maritime Museum ; Mr. W. Palin Elderton, chairman of the British Insurance Association, actuary and manager of the Equitable Life Assurance Society ; Mr. W. Reavell, lately president of the British Engineers' Association ; Dr. W. G. Savage, county medical officer of health, Somerset ; Dr. T. F. Sibly, vice-chancellor of the University of Reading, member of the Advisory Council of the Department of Scientific and Industrial Research ; Mr. J. P. Ross-Taylor, chairman of the Highland and Agricultural Society ; Dr. C. McM. Wilson, dean of St. Mary's Hospital Medical School ; Mr. D. R. Wilson, H.M. Chief Inspector of Factories, Home Office.

C.B. : Major-General W. P. MacArthur, honorary physician to the King, commandant and director of studies, Royal Army Medical College, Millbank ; Major-General A. E. Davidson, director of mechanization, War Office. *C.M.G.* : Mr. F. Hemming, secretary to the International Committee for the Application of the Agreement regarding Non-intervention in Spain, who is secretary of the International Commission of Zoological Nomenclature ; Dr. P. H. Manson-Bahr, consulting physician to the Colonial Office ; Dr. J. D. Tothill, director of agriculture, Uganda Protectorate. *C.I.E.* : Mr. C. F. Bell, chief conservator of forests, Central Provinces and Berar ; Lieutenant-Colonel G. T. Burke, lately secretary, Medical Council of India; Dr. C. W. B. Normand, director-general of observatories, Government of India; Khan Bahadur Shapurji Nasarvanji Jamshedji Ratnagar, lately conservator of forests, Southern Circle, Bombay. *C.B.E.:* Mr. J. B. Beresford, secretary of the University Grants Committee and also of the Standing Commission on Museums and Galleries; Mr. J. Dewar, surveyor-general, Federated Malay States and Straits Settlements; Mr. H. J. G. Griffin, secretary of the Council for the Preservation of Rural England; Mr. A. L. Hetherington, assistant secretary of the Department of Scientific and Industrial Research; Dr. J. W. Mellor, lately director of the British Refractories Research Association; Dr. E. C. Snow, joint honorary secretary of the Royal Statistical Society; Dr. A. H. Thompson, professor of history in the University of Leeds, and member of the Royal Commission on Historical Monuments (England).

O.B.E.: Captain T. W. Barnard, director of the Barnard Institute of Radiology, Madras; Mr. T. R. Charlton, commissioner of lands, Crown surveyor, and chairman, Mining Board, Fiji; Mr. R. A. Farquharson, geologist in charge, Water-Boring Scheme, Somaliland Protectorate; Dr. R. S. G. Knight, manager and deputy superintendent, Royal Naval Cordite Factory, Holton Heath; Mr. F. Leney, lately curator, Norwich Castle Museum and Art Gallery; Mr. H. M. O Lester, deputy director, Sleeping Sickness Service, Nigeria; Mr. W. B. Rimmer, acting director of the Solar Observatory at Mount Stromlo, Commonwealth of Australia; Ram Chandra Srivastava, director of the Imperial Institute of Sugar Technology, Cawnpore, United Provinces, India; Dr. V. E. Wilkins, principal, Ministry of Agriculture and Fisheries. *M.B.E.:* Mr. J. Coutts, lately curator, Royal Botanic Gardens, Kew; Mr. W. A. Fyffe, public analyst for the Isle of Man; Mr. W. B. Mercer, agricultural organizer for Cheshire and principal of the Reaseheath Farm Institute; Mr. A. E. Spencer, computor, Land and Survey Department, Uganda. *Kaisar-i-Hind Gold Medal:* Dr. R. R. Stewart, principal of Gordon College, Rawalpindi, Punjab.

Indian Science Congress Association at Calcutta

THE twenty-fifth annual meeting of the Indian Science Congress Association, to which the British Association has sent a large delegation, opened at Calcutta on January 3 under the presidency of Sir James Jeans. Lord Rutherford was to have been president, and that portion of the address which he had prepared, representing his final word on what he used to describe as "the new alchemy", is printed on pp. 58–61 of this issue of NATURE. Sir James Jeans made his address brief, so that he might read to the assembled Congress a portion of that prepared by Lord Rutherford. In the first part of his address, Sir James paid eloquent tribute to the man whose place he was filling—"one of the greatest scientists of all time". He spoke of his greatness, his simplicity and sincerity, and remarked on his genius for friendship and good comradeship, an aspect of Rutherford's character which has also been demonstrated in the tributes to his memory we have been privileged to publish. In spite of the honours showered upon him, he was always "unassuming and ready to listen patiently to even the youngest and most inexperienced of his pupils or fellow-workers". Speaking of the work he accomplished, Sir James said that, "in his flair for the right line of approach to a problem, as well as in the simple directness of his methods of attack, he often reminds us of Faraday, but he had two great advantages which Faraday did not possess—first, exuberant bodily health and energy, and second, the opportunity and capacity to direct a band of enthusiastic co-workers. Great though Faraday's output of work was, it seems to me that to match Rutherford's work in quantity as well as in quality, we must go back to Newton".

Progress of Science in India

IN the second part of his address, Sir James Jeans referred to the progress of science during the quarter of a century since the Congress was founded, and to the contributions of Indian workers. Restricting himself to the field of mathematics and physics, he mentioned the remarkable discoveries made in pure mathematics by Ramanujan in his short life; the work of Sir Venkata Raman in sound and the theory of music, and his discovery of the spectral effect now known everywhere by his name; the investigations of Prof. M. Saha in astrophysics, "which gave us our first clear understanding of the meaning of stellar spectra, and so unlocked the road to vast new fields of astronomical knowledge"; and also the work of many Indians, especially Chandrasekhar and Kothari, on conditions in the interiors of stars. Many, other than mathematicians and physicists, would also be thinking of the great experimental skill of the late Sir Jagadis Chandra Bose. In 1911, Sir James said, there were no Indian-born fellows of the Royal Society; now there are four. In 1911, the Royal Society published no papers by Indians; in 1936, the Society published ten. The past twenty-five years have been one of the greatest periods in the history of science, a period of unprecedented progress in which India has taken its part and which has seen the remarkable growth of India as a scientific nation.

Policy and the Aborigines in Australia

IT is to be hoped that no apparent difference of opinion among anthropologists as to the ultimate fate of the Australian aborigines will be allowed to obscure the plain present duty of the Commonwealth Government in the matter of reform of policy and methods of administration. The report of Dr. Donald F. F. Thomson, research fellow of the University of Melbourne, to the Commonwealth Government on his observations as a special patrol officer for a period of fifteen months among the natives of Arnhem Land in the Northern Territories is uncompromising in its directness. He recommends, according to a dispatch of the Canberra correspondent of *The Times* in the issue of December 30, that the remains of the tribalized natives of the Northern Territories, who come under the control of the Commonwealth Government, should be segregated in an inviolable reserve; and that legislation similar to that in force in New Guinea for the protection of natives should be imposed in their interest. Watering depots for pearlers on the coast of Arnhem Land should be abolished. The policy of administering native justice should be revised; the police should not be allowed to act as protectors; and special courts for the aborigines should be established. It is recommended further that the Commonwealth Government should set up a Department of Native Affairs under a trained protector and staffed by men trained to apply anthropological methods; while eventually the administration of native affairs throughout Australia should be brought under one control. The Arnhem Land natives should not be permitted to leave the reserve, and missions should be requested to remove their stations to the outskirts of the reserve to prevent the entry of outside influence.

SETTING aside the larger question of the unification of control of aboriginal affairs throughout Australia, for which much is to be said, Dr. Thomson's recommendations represent the absolute minimum of immediate and urgent reform essential for the preservation of the aborigines of the Northern Territories. Mr. McEwen, Commonwealth Minister of the Interior, is reported to have expressed the view that, as it is inevitable that sooner or later the aborigines must come into contact with civilization, they should be prepared for it. Apparently he accepts an opinion attributed to "some anthropologists" that the segregation of tribalized natives "is undesirable and impracticable". Without a more precise statement of its authority, such an opinion carries little conviction; and it is contrary to the views of anthropologists most competent to speak. How far segregation is practicable and likely to be beneficial depends upon the will of the Australian people to ensure that full effect shall be given to that policy, which past experience shows alone to be capable of affording the aboriginal an opportunity to survive. Segregation does not necessarily entail a state of stagnation in which the aboriginal tribe is a museum piece. When once conditions favourable, and indeed essential, to the continued existence of the aborigines have been secured, it will be possible to plan their future and guide development along lines consistent with their character and tradition.

Segregation in Polish Universities

NEARLY one thousand outstanding scholars in leading universities in the United States have signed an open letter to their colleagues in some of the universities of Poland, where Jewish students are now segregated from their fellows, and repeated acts of violence are reported against them and Jewish professors. It is realized that the university authorities are faced with great difficulties on account of religious and racial differences, but to bring these conditions of strife into the classrooms and laboratories by adoption of a policy of segregation violates the principle of intellectual freedom upon which university life must be based. "Such discrimination", the signatories protest, "seems to us alien to the spirit of academic freedom and of the free co-operation in the pursuit of knowledge that is so essential to the world of scholarship". The distinguished members of the faculties of Polish institutions of higher learning who have raised their voices against this discrimination will, it is hoped, be encouraged by this support of their American colleagues to continue their efforts to maintain the high tradition of such institutions in the free republic of scholarship. Sympathy with suffering, and sensitiveness to injustice, are attributes which distinguish man from all his fellow creatures; and any deliberate action which evokes them cannot be other than a reversion to primitive instincts. In this twentieth century it is depressing to see the law of the jungle being accepted and applied to secure racial and national domination, when such great powers and opportunities exist for the progressive evolution of man's higher nature. Those of us who believe in a nobler destiny for the human race than has yet been reached find a certain amount of comfort in the dismay expressed by American scholars at the extension to Poland of a spirit of intolerance foreign to every principle for which a university should stand.

Institute of Economic and Social Research

ANNOUNCEMENT is made of the formation of a new Institute of Economic and Social Research. Sir Josiah Stamp is to be the first president of the Institute, and Prof. N. F. Hall, professor of political economy in the University of London (University College), is to be director. Among the functions of the Institute are the carrying out of research, either by its own staff or by others temporarily associated with it, into the facts and problems of contemporary human society, and the publication of the results of researches, subject to adequate safeguards for the impartial and scientific character of these publications. Financial support for the Institute is being provided by the Sir Halley Stewart Trust, the trustees of the late Lord Leverhulme, the Pilgrim Trust and the Rockefeller Foundation. An annual income has been guaranteed of £10,000 for five years, and £5,000 for two years after. The offices of the Institute will be at 32 Gordon Square, London, W.C.1.

Physical Society's Exhibition

THE Catalogue of the Physical Society's Exhibition, held in the Imperial College of Science and Technology on January 4, 5 and 6, covers 226 pages, has many illustrations and is well arranged. The paging is on the bottom edge of the page, the number of the stall on the top outer corner and the name of firm exhibiting on the top inner corner. It is divided into two sections, Trade (177 pages) and Research (36 pages), and an alphabetical list of exhibitors in each section is provided which gives also the number of the stall. A four-page index of the instruments exhibited with indication of the pages on which they are described is also provided. Reference to the catalogue is therefore easy and quick. New exhibits are indicated in the catalogue by an asterisk and on the stalls by a red star. As compared with last year, the exhibits in the Research Section have nearly doubled, while those in the Trade Section are about the same with a somewhat larger proportion of red stars. Some of the illustrations convey more information as to the working parts of the instruments than in past years, and are more useful to prospective buyers. Those on pp. 28, 165, 176 and 179 may be taken as examples. Discourses were delivered on January 4 by Captain G. C. C. Damant on "Diving in Deep Water and Shallow", on January 5 by Prof. A. F. C. Pollard on "Mechanical Amplification of Small Displacements" and by Sir Richard Gregory on "Science and Citizenship" jointly to the visitors to the Exhibition and to those attending the Exhibition of School Apparatus by the Science Masters' Association.

Engineering and Economics

IN an address to the Society of Engineers on October 4, entitled "Engineering and the New Economics", Dr. H. Chatley suggested that the engineer can contribute to the solution of economic problems of to-day in three ways. In the first place, the engineer can study the problem in terms of realities, such as goods, energy and services, and endeavour to disentangle them from the cobwebs of finance. Secondly, some engineers by entering politics can assist in spreading ideas on the realities of life. Thirdly, the engineer both by speech and by writing can help to explode some old fallacies and to educate the public in newer ideas and especially in that of the impartial application of scientific method to public affairs. Dr. Chatley illustrated his argument in respect of the last point by outlining in some detail the way in which the engineer can assist in the development of a sound fiscal policy in regard to coal and oil as well as in regard to the prevention of atmospheric pollution, the preservation of amenities, the question of values and prices, international debts, and population limits, and concluded by asserting that it is the duty of the engineer to understand the problems which have been raised by the misapplication by others of his skill. Scientific method should play an important part in citizenship since the classification of facts, the recognition of their sequence and significance and the habit of forming an unbiased judgment upon the facts which are characteristic of the scientific frame of mind are also essentials of good citizenship.

Awards for War Inventions

THE final report of the Royal Commission on Awards to Inventors, which has now been published (Cmd. 5594) shows that, in all, 1,834 applications were received by the Commission, of which 369 were dealt with by the Commission direct. Of the remaining 1,465, which were in the first instance considered by the Investigating Committee, 846 were withdrawn or apparently abandoned, 75 were referred to and later heard by the Commission and 544 were rejected by the Committee as having no reasonable chance of success. In 200 of them the claimant exercised his right of a personal appearance before the Investigating Committee. The total amount of awards was about £1,500,000, and a summary of the awards is appended to the report. Claims submitted to the Commission before the final date fixed by Royal Warrant (March 31, 1932) were virtually determined by December 31, 1933, but there were at that date certain claims the position of which had not been finally determined. The claims in question have since been otherwise disposed of, but while further sittings of the Commission were not necessary, the submission of a final report was delayed. The actual sittings of the Commission covered a period of fifteen years, and in that time the Commission lost by death its chairman, Lord Tomlin, as well as two members, Mr. A. C. Chapman and Prof. W. E. Dalby.

Commonwealth Fund Fellowships

THIRTY-FOUR of these fellowships, enabling British university men to devote two years to study and travel in the United States of America, are offered for award in 1938. Twenty-four are open to candidates of British descent, domiciled in the United Kingdom, who are graduates of universities therein, unmarried and less than thirty years of age; two to graduates of a university in a British dominion or colony; five are 'service fellowships' open only to candidates holding Government appointments in the British Empire over-seas; and three are Home Civil Service fellowships. The Committee of Award (chairman, Sir Walter H. Moberly) give primary consideration to intellectual ability, personality and initiative; account is also taken of character and health. Application, in the prescribed form, approved by the authorities of the college or university of which the candidate is or has been a member, must reach the Secretary to the Committee (35 Portman Square, W.1) by February 1. In 1937, awards were made to candidates from Cambridge (5), Cardiff, Glasgow, Liverpool (2), London (4), Manchester (2), Oxford (9), Reading, St. Andrews, New Zealand and South Africa. The subjects of study were very various, comprising: physics (3), chemistry (2), biophysics, zoology, physiology, medicine (2), engineering, architecture (2), law, political science, economics, international relations, education, modern languages, English literature, American literature, theology. The fellowships, in some respects complementary to the Rhodes scholarships, were established with the view of promoting mutual amity and understanding between Great Britain and the United States.

Constable's Portrayal of Weather

MR. L. C. W. Bonacina's paper on "John Constable's Centenary: His Position as a Painter of Weather" (*Quart. J. Roy. Meteor. Soc.*, October 1937) is a notable contribution to that affiliation of the Nature studies of the artist and scientific worker which is so much to be desired. The character of the country in which Constable was born and bred evidently influenced his practice of emphasizing cloud effects in landscape. The Suffolk countryside where the celebrated pictures of Flatford Mill, Dedham Mill and Stoke-by-Nayland were painted is the plain seen by the traveller on the London and North-Eastern Railway when crossing the River Stour above Manningtree. Here the land presents none of those emphatic forms which in rugged scenery tend to concentrate attention on the lower half of the confronting hemisphere, so the eye ranges freely over the sky, and the cloud is as important as the field in the composition of the picture. Originals of Constable's paintings are readily accessible in the National Gallery and the Victoria and Albert Museum, and many are familiar as engravings, so that Mr. Bonacina's judgments can easily be tested. We welcome his conclusion that Constable's generalization of particular types of cloud in a manner not possible for photography is of service to the meteorologist. The analysis of certain pictures in which transitory forms are so perfectly depicted as to introduce a cinematic effect is a notable contribution to art criticism. It is indeed entirely appropriate that the student of natural science should thus contribute to the understanding of landscape painting, for the critical faculty is as a rule more highly developed in the man of science than in the artist—who does more than he knows.

A Guide to Fishes

REGULAR visitors to the Fish Gallery at the British Museum (Natural History) during recent years have watched with interest the rearrangement under the supervision of Mr. J. R. Norman. The large number of new casts and models, due to the skill of Mr. S. Stammwitz, have resulted in an exhibition illustrative of fish life that would be difficult to improve upon with present-day resources. The first part of the new guide to the Gallery contains a general account of classification, the scheme adopted being that proposed by Dr. C. Tate Regan (British Museum (Natural History). Illustrated Guide to the Fish Gallery. By J. R. Norman. Pp. x+175+6 plates. London: Trustees of the British Museum, 1937. 1*s.* 6*d.*). A wealth of interesting notes on habits and on fisheries turns what might otherwise be a rather dull catalogue into fascinating matter for general reading. The second and rather larger portion of the book is taken up with descriptions of the special exhibits, of which there are eighteen. These are evidently such as will cater for the needs of most visitors. They include such items as the crucifix fish, of interest to the credulous rather than to the serious student, who will find more to his taste in the section (and exhibit) devoted to breeding habits and development of coloration. This is an excellent guide book, but it is more than that; it is an elementary text-book of fish life. It is well written and well illustrated, in which connexion a word of praise must be spared for Lieut.-Col. W. P. C. Tenison's accurate and charmingly executed drawings.

The School Certificate Examination

THE School Certificate Examination, its merits and demerits and how it might be improved: these are matters which so closely concern so many people—parents and employers as well as school and university teachers and administrators—that the National Union of Teachers has performed an important public service in printing and circulating Sir Philip Hartog's address at its Portsmouth Conference. Sir Philip, than whom a more competent critic could scarcely be found, exposes manifold weaknesses of the examination as at present administered. He discusses such questions as: What does passing the examination imply in terms of what each successful candidate will be able to do? What do the examiners suppose they are trying to test? What of the validity and consistency of the test? More than a quarter of the candidates fail: does this not point to serious maladjustment between education and examination? He makes five definite proposals for reform: (i) classify tests in such a way as to show employers in what cases they can rely on a pass as showing the possession of definite utilizable skills; (ii) give to each candidate a certificate characterizing his or her performance in each subject; (iii) abolish the group system in so far as it hampers the school in determining the examination programme to suit each child after investigation of individual aptitudes; (iv) supplement the school certificate by a cumulative school record; (v) protect certain subjects, such as English literature, history and general science, from examination pressure, providing at the same time for their compulsory inclusion in the curriculum and school time-tables.

Gardens for Busy Enthusiasts

THERE must be a considerable body of garden enthusiasts who have only a limited time in which to maintain horticultural beauty around their homes. Professional cares of the specialist often diminish the hours of leisure which might be devoted to gardening, or other causes may intervene. Mr. R. S. Lynch's paper on "Gardens of Easy Maintenance" (*J. Roy. Hort. Soc.*, 62, 9, 377–393, Sept. 1937) is a most useful help for such enthusiasts. Lawns are particularly insistent in their demands for attention, and for those who regard them as essential to garden beauty, Mr. Lynch has many suggestions for their more facile control. A pleasing arrangement of alpines upon a paved bank requires little attention, though it ministers well to formal artistry. The horticultural qualities of many perennial plants which demand neither pruning, frequent division, nor staking, are discussed in detail in the paper, whilst the claims of an evergreen garden are also considered. A large amount of practical information, which should help to meet a pressing modern need, is here portrayed.

Timber Seasoning in Australia

TIMBER seasoning has made very considerable progress in many countries of the world since the Great War. It was during that War that a great deal of research work in seasoning by means of kiln-drying was undertaken, more especially perhaps in Great Britain and in India. Owing to the enormous consumption of timber upon the War fronts all seasoned material was absorbed in a comparatively short space of time; and since then it is not an overstatement to say that good seasoned material of high quality is very difficult to obtain for many species of timbers. In this new departure of utilizing the kiln for drying timbers, Australia has not been behind other parts of the Empire. In 1933 the Division of Forest Products of the Council for Scientific and Industrial Research published as a pamphlet Part 1 of "A Guide to the Seasoning of Australian Timbers", in which it was pointed out that timbers of different species frequently differ so widely in physical properties that it is impossible to prescribe a general set of conditions for air-drying or kiln-drying for all timbers, or even for all sizes of one timber. Part 2 of this Guide has been recently issued (Div. of For. Products, Pamphlet No. 68, Technical Paper, No. 22. Melbourne, 1937) written by W. L. Greenhill and A. J. Thomas. The work of determining suitable kiln schedules for various species and sizes of timber is being carried out in laboratory kilns, supplemented by information operated by the Queensland forest service. Based on the results of the work carried out since the publication of Part 1, seasoning notes and suggested schedules for twenty-two additional species are given in the present pamphlet.

Tuberculosis in the Far East

THE problem of tuberculosis was one of the subjects dealt with at the Conference of Far Eastern Countries on Rural Hygiene last August (League of Nations. Health Organisation. Report of the Intergovernmental Conference of Far-Eastern Countries on Rural Hygiene. Held at Bandoeng (Java), August, 1937. London: George Allen and Unwin, Ltd. 2*s*. 6*d*.). Tuberculosis is recognized as being one of the scourges in Eastern countries. Unfortunately, there is an almost complete absence of accurate data concerning the extent and severity of the disease in rural areas. The importance of carrying out preliminary surveys and sample tuberculin tests in the country is advocated. Financial limitations make it important that an anti-tuberculosis campaign should be simple and adapted to local conditions, and the gradual establishment of a network of rural dispensaries would appear advisable. The establishment of sanatoria, in the Western sense, would not seem to be applicable, but simpler institutions are suggested. A scheme for mass research on tuberculin sensitiveness was drafted.

Chinese Medicine and the Pangolin

The pangolin or scaly ant-eater (*Manis pentadactyla dalmanni*) is the most primitive of Chinese mammals, and although it is fully protected by law in the colony and island of Hong-Kong, the demand for its carcass makes more extensive protection in South China necessary (*Hong Kong Naturalist*, July 1937, 79). The animal itself is eaten, but a greater danger arises from the belief that the scales have medicinal value. Fresh scales are never used, but dried scales are roasted, ashed, cooked in oil, butter, vinegar, boy's urine, or roasted with earth or oyster-shells, to cure a variety of ills. Amongst these are excessive nervousness and hysterical crying in children, women possessed by devils and ogres, malarial fever and deafness. So much are pangolin scales in request for these purposes that yearly the scales from some 4,000 or 5,000 individuals were imported from Java, with a value of 3,700 guilders. But recent regulations in Java, which prohibit capturing and killing of pangolins and the export of scales, will turn the attention of the Chinese medicine men more forcibly towards the native product.

James Eights: a Pioneer Antarctic Naturalist

DR. W. T. CALMAN has done worthy service to the memory of an American naturalist of the early nineteenth century in his presidential address to the Linnean Society (*Proc. Linn. Soc.*, 149, 171; 1937). The accuracy of the descriptions and drawings made by James Eights, his discovery of a ten-legged pycnogon (*Decolopoda*), in which no one believed until the rediscovery of the species by the Scottish National Antarctic Expedition almost seventy years later, his discovery of a new seal and a new dolphin, neither of which he named, his description of the breeding of the king penguin, and of the South Shetland Islands, all mark him as a naturalist of keen perception. It is unfortunate that the appearance of his descriptions in journals not readily accessible should have obscured and delayed the recognition of his merit, and more sad to learn that in his own country he dropped out of the current and lived for a quarter of a century, until his death in 1882, in loneliness, obscurity and poverty.

Spectrograms of Nova Herculis 1934

THE editors of the *Astrophysical Journal* in 1935 collected data as to the spectrograms of Nova Herculis 1934 available at different observatories, partly with a view to the ultimate production of an atlas showing the changes day by day in the spectrum of the star during the first few months after the initial outburst. On the appointment of a Nova Sub-commission in the Commission of Stellar Spectra of the International Astronomical Union, this material was handed to Prof. F. J. M. Stratton as chairman of that Sub-commission. Further data as to the observational material available were secured, and now the spectrum of Nova Herculis for nearly every day is available from one source or another from the head of the Balmer series to $H\alpha$. The Solar Physics Committee at Cambridge has approved the production by the staff of the Solar Physics Observatory of an atlas showing daily changes over that range of spectrum. It is hoped to print the whole atlas on 16 stiff cards—one quarter of the spectrum on each card and one card for each month. The cost will depend on the number of subscribers to the atlas, and subscribers may be asked to pay as much as 25 shillings. If sufficient support is forthcoming, it is hoped to start work on the atlas early in 1938.

Rabies Prevention in India

DETAILS of the preventive treatment of rabies at the Pasteur Institute of India, Kasauli, are given in the thirty-fifth annual report for the year 1935 by the director, Dr. R. O. A. Smith. The total number of patients attending the Institute and its centres was 21,898, an increase of 657 patients as compared with the previous year, of whom 16,627 received the complete course of treatment. There were 86 deaths among these, a percentage death-rate of 0·52, which compares with 0·49 for the previous year. In addition, 1260 courses of vaccine for the prophylactic treatment of animals were issued during the year. The vaccine employed is a carbolized 5 per cent emulsion of sheep's brain prepared from sheep infected with the Paris fixed virus.

Twenty-Five Years of Research in Dairying

TWENTY-FIVE years ago the National Institute for Research in Dairying, University of Reading, was founded, and to celebrate the event an "Anniversary Review", compiled by the staff of the Institute, has been issued. This booklet presents a short history of the origin and development of the Institute, with a brief account of its present relationship with the farm, the dairying industry generally and the public. A summary is also given of the many and varied investigations carried out at the Institute, or in collaboration with other research centres, mainly between 1923 and the commencement of the present year.

Announcements

PROF. RICHARD KUHN will deliver the sixth Pedler Lecture of the Chemical Society at the London School of Hygiene and Tropical Medicine on January 27 at 5.30 p.m. The subject of the lecture will be "Synthesis of Polyenes".

THE medical faculty of the University of Zurich has elected Dr. William Cortedge of Rochester, U.S.A., an honorary doctor in recognition of his work on applied physics in medicine especially in roentgenology.

THE Rockefeller Foundation of New York has decided to award Profs. A. Kluyve of Delft and L. S. Ornstein of Utrecht financial support for five years for their radiobiological investigations, which have already been supported by the Foundation for three years.

THE Women's Medical Association of New York City offers the Mary Putnam Jacobi Fellowship (1000 dollars for one year) which is available for post-graduate work in the medical sciences. The fellowship is open to any woman graduate of an approved medical school. Further information can be obtained from Dr. Phoebe Du Bois, 150 East 73rd Street, New York.

THE Ophthalmological Society of the United Kingdom has instituted a Treacher Collins Prize of £100, which will be awarded every three years for the best essay submitted on a subject selected by the Council. It will be open to medical practitioners of any nationality, but the essay must be in English. The first subject selected is cerebro-spinal disease and its relation to the optic nerve. Essays should be submitted to the honorary secretary, 5 Racquet Court, Fleet Street, E.C.4, before December 31, 1938.

DR. HERMANN WINTZ, professor of obstetrics and gynæcology at Erlangen, has been awarded the Carlos Heiser Medal by the International Commission of Radiologists and Roentgenologists.

AN Italian society of metaphysics has recently been founded in Rome with a presidential council consisting of Prof. Ferdinando Cazzamalli, Dr. Luigi R. Sanguineti, Prof. G. Schepia and Dr. Emilio Servado. Further information can be obtained from the secretary, Dr. L. R. Sanguineti, Via Serbelloni 2, Milan.

THE twenty-seventh Dutch Congress of Natural Science and Medicine will be held at Nymwegen on April 11–13, 1939, under the presidency of Prof. G. Holst of Eindhoven. Further information can be obtained from the general secretary, Dr. D. Coelingh, Bussum, Holland.

A LAW for the reorganization of the University of Brazil and construction of the University City at Rio de Janeiro recently passed the House of Deputies. The Federal Government is now in charge of the construction of the University City, which will include the faculties of philosophy, education, fine arts, engineering, mining and metallurgy, chemistry and pharmacy, law, politics and economy, agriculture, veterinary medicine and music. There will also be a hospital.

"PHOTOMICROGRAPHY with the Vickers Projection Microscope" is the title of a booklet published by Messrs. Cooke, Troughton and Simms, Ltd., Buckingham Works, York, the present makers of the instrument, which was originally designed and manufactured at the Erith Works of Messrs. Vickers-Armstrong, Ltd. The apparatus is fully described, together with the electrical equipment and instructions for assembly. The manner of using and maintenance are described, and chapters are devoted to the theory of the microscope and preparation of specimens. The booklet contains much information on the subject of photomicrography and the use of the microscope in steel works practice, apart from the Vickers instrument, and is fully illustrated.

ASSISTANCE in the selection of suitable scientific books for public libraries is always welcomed. We are glad to see, therefore, that Prof. B. W. Holman, who is a member of the Brentford Borough Council, has contributed to the January issue of the *Fordwick*—a quarterly list of books added to the Brentford and Chiswick Public Libraries—a short article on recent books on social and other non-technical aspects of science.

"T. LL. H." informs us that in his review of Sir Frederick Maurice's "Life of Lord Haldane", the date of the appointment of the Royal Commission (NATURE, Dec. 11, p. 989) should have been 1909, not 1907.

ERRATUM. In the last line but one of the letter by Dr. A. S. Parkes entitled "Terminology of Sex Hormones" in NATURE of January 1, p. 36, for "*thryotrophic*" read "*thyrotrophic*".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

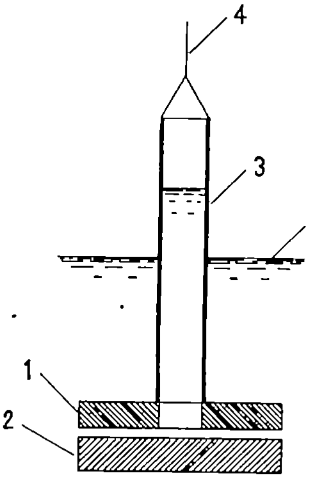
NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 83.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Viscosity of Liquid Helium below the λ-Point

THE abnormally high heat conductivity of helium II below the λ-point, as first observed by Keesom, suggested to me the possibility of an explanation in terms of convection currents. This explanation would require helium II to have an abnormally low viscosity; at present, the only viscosity measurements on liquid helium have been made in Toronto[1], and showed that there is a drop in viscosity below the λ-point by a factor of 3 compared with liquid helium at normal pressure, and by a factor of 8 compared with the value just above the λ-point. In these experiments, however, no check was made to ensure that the motion was laminar, and not turbulent.

The important fact that liquid helium has a specific density ρ of about 0·15, not very different from that of an ordinary fluid, while its viscosity μ is very small comparable to that of a gas, makes its kinematic viscosity $\nu = \mu/\rho$ extraordinary small. Consequently when the liquid is in motion in an ordinary viscosimeter, the Reynolds number may become very high, while in order to keep the motion laminar, especially in the method used in Toronto, namely, the damping of an oscillating cylinder, the Reynolds number must be kept very low. This requirement was not fulfilled in the Toronto experiments, and the deduced value of viscosity thus refers to turbulent motion, and consequently may be higher by any amount than the real value.



The very small kinematic viscosity of liquid helium II thus makes it difficult to measure the viscosity. In an attempt to get laminar motion the following method (shown diagramatically in the accompanying illustration) was devised. The viscosity was measured by the pressure drop when the liquid flows through the gap between the disks 1 and 2; these disks were of glass and were optically flat, the gap between them being adjustable by mica distance pieces. The upper disk, 1, was 3 cm. in diameter with a central hole of 1·5 cm. diameter, over which a glass tube (3) was fixed. Lowering and raising this plunger in the liquid helium by means of the thread (4), the level of the liquid column in the tube 3 could be set above or below the level (5) of the liquid in the surrounding Dewar flask. The amount of flow and the pressure were deduced from the difference of the two levels, which was measured by cathetometer.

The results of the measurements were rather striking. When there were no distance pieces between the disks, and the plates 1 and 2 were brought into contact (by observation of optical fringes, their separation was estimated to be about half a micron), the flow of liquid above the λ-point could be only just detected over several minutes, while below the λ-point the liquid helium flowed quite easily, and the level in the tube 3 settled down in a few seconds. From the measurements we can conclude that the viscosity of helium II is at least 1,500 times smaller than that of helium I at normal pressure.

The experiments also showed that in the case of helium II, the pressure drop across the gap was proportional to the square of the velocity of flow, which means that the flow must have been turbulent. If, however, we calculate the viscosity, assuming the flow to have been laminar, we obtain a value of the order 10^{-9} C.G.S., which is evidently still only an upper limit to the true value. Using this estimate, the Reynolds number, even with such a small gap, comes out higher than 50,000, a value for which turbulence might indeed be expected.

We are making experiments in the hope of still further reducing the upper limit to the viscosity of liquid helium II, but the present upper limit (namely, 10^{-9} C.G.S.) is already very striking, since it is more than 10^4 times smaller than that of hydrogen gas (previously thought to be the fluid of least viscosity). The present limit is perhaps sufficient to suggest, by analogy with supraconductors, that the helium below the λ-point enters a special state which might be called a 'superfluid'.

As we have already mentioned, an abnormally low viscosity such as indicated by our experiments might indeed provide an explanation for the high thermal conductivity, and for the other anomalous properties observed by Allen, Peierls, and Uddin[2]. It is evidently possible that the turbulent motion, inevitably set up in the technical manipulation required in working with the liquid helium II, might on account of the great fluidity, not die out, even in the small capillary tubes in which the thermal conductivity was measured; such turbulence would transport heat extremely efficiently by convection.

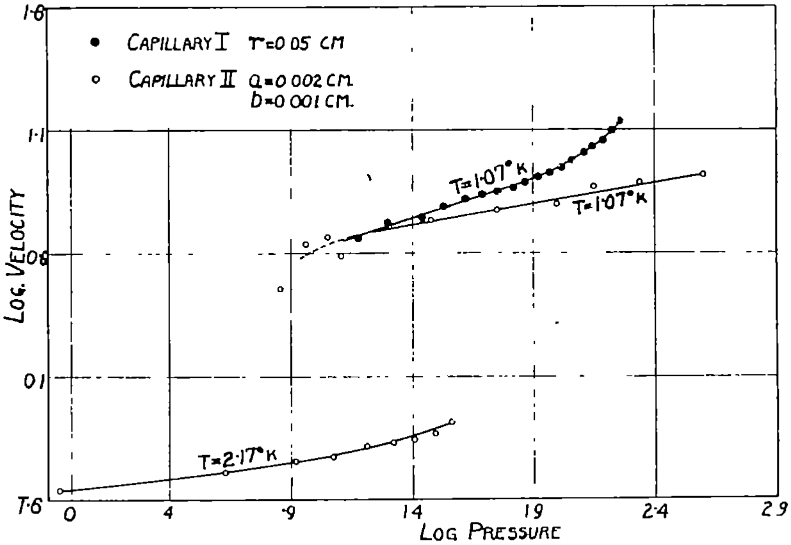
Flow of Liquid Helium II

A SURVEY of the various properties of liquid helium II has prompted us to investigate its viscosity more carefully. One of us[1] had previously deduced an upper limit of 10^{-5} C.G.S. units for the viscosity of helium II by measuring the damping of an oscillating cylinder. We had reached the same conclusion as Kapitza in the letter above; namely, that due to the high Reynolds number involved, the measurements probably represent non-laminar flow.

The present data were obtained from observations on the flow of liquid helium II through long capillaries. Two capillaries were used; the first had a circular bore of radius 0·05 cm. and length 130 cm. and drained a reservoir of 5·0 cm. diameter; the second was a thermometer capillary 93·5 cm. long and of elliptical cross-section with semi-axes 0·001 cm. and 0·002 cm., which was attached to a reservoir of 0·1 cm. diameter. The measurements were made by raising or lowering the reservoir with attached capillary so that the level of liquid helium in the reservoir was a centimetre or so above or below that of the surrounding liquid helium bath. The rate of change of level in the reservoir was then determined from the cathetometer eye-piece scale and a stop-watch; measurements were made until the levels became coincident. The data showing velocities of flow through the capillary and the corresponding pressure difference at the ends of the capillary are given in the accompanying table and plotted on a logarithmic scale in the diagram.



Capillary I		Capillary II			
$T = 1·07°$ K.		$T = 1·07°$ K.		$T = 2·17°$ K.	
Velocity (cm./sec.)	Pressure (dynes)	Velocity (cm./sec.)	Pressure (dynes)	Velocity (cm./sec.)	Pressure (dynes)
13·9	183·5	8·35	402	0·837	36·6
11·5	154·5	6·92	218	0·757	31·3
10·3	127·7	6·88	143	0·715	26·1
9·0	105·0	6·30	101	0·685	21·1
8·2	83·5	6·05	56	0·655	16·4
7·5	65·7	5·55	30	0·609	12·1
6·9	49·3	4·70	11·3	0·570	8·3
6·1	34·1	4·39	9·2	0·525	4·3
5·2*	20·3	3·92	13·0	0·433	0·9
4·5*	15·2	2·88	7·2		

The following facts are evident:

(*a*) The velocity of flow, q, changes only slightly for large changes in pressure head, p. For the smaller capillary, the relation is approximately $p \propto q^4$, but at the lowest velocities an even higher power seems indicated.

(*b*) The velocity of flow, for given pressure head and temperature, changes only slightly with a change of cross-section area of the order of 10^3.

(*c*) The velocity of flow, for given pressure head and given cross-section, changes by about a factor of 10 with a change of temperature from 1·07° K. to 2·17° K.

(*d*) With the larger capillary and slightly higher velocities of flow, the pressure-velocity relation is approximately $p \propto q^3$, with the power of q decreasing as the velocity is increased.

If, for the purpose of calculating a possible upper limit to the viscosity, we assume the formula for laminar flow, that is, $p \propto q$, we obtain the value $\eta = 4 \times 10^{-9}$ C.G.S. units. This agrees with the upper limit given by Kapitza who, using velocities of flow considerably higher than ours, has obtained the relation $p \propto q^2$ and an upper limit to the viscosity of $\eta = 10^{-9}$ C.G.S. units.

The observed type of flow, however, in which the velocity becomes almost independent of pressure, most certainly cannot be treated as laminar or even as ordinary turbulent flow. Consequently any known formula cannot, from our data, give a value of the 'viscosity' which would have much meaning. It may be possible that the liquid helium II slips over the surface of the tube. In this case any flow method would be incapable of showing the 'viscous drag' of the liquid.

With regard to the suggestion that the high thermal conductivity of helium II might be explained by turbulence, we have calculated that the flow velocity necessary to transport all the heat input over the observed temperature gradient in the Allen, Peierls and Uddin experiments[2] is about 10^4 cm./sec. On the other hand, the greatest flow velocity produced by manipulation and by the pressure difference along the thermal conduction capillary will not be likely to be greater than 50 cm./sec. It seems, therefore, that undamped turbulent motion cannot account for an appreciable part of the high thermal conductivity which has been observed for helium II.

Some Experiments at Radio Frequencies on Supraconductors

MEASUREMENTS were made on an extruded tin wire carrying an alternating current of a frequency of about 200 kilocycles per second superposed upon a direct current. The resulting magnetic field at the surface of the wire was thus caused to pulsate cyclically.

When the temperature of the wire was slightly below the transition temperature, the pulsation in field tended to carry the material through the transition between the normal resisting and the supraconducting states. It was found that under these conditions the potential difference between the ends of the specimen contained a component of double the frequency of the alternating current and of the magnitude to be expected if the resistivity of the material in the outer portion of the wire was able to follow the pulsations in the magnetic field without an appreciable lag.

The double-frequency component was present only in that narrow range of combinations of temperature and current for which a pulsation in resistance was to be expected. If there is any lag in the destruction of the supraconducting state by a magnetic field and in its re-establishment, it can be stated that the lags are small as compared with 2 micro-seconds.

Other measurements at radio frequencies up to 3,000 kilocycles per second indicate that for tin and tantalum the transition temperatures are the same for direct currents equal in magnitude to the root-mean-square of the high-frequency currents. When cooled below the transition temperatures, these materials offered no detectable resistance to currents of these frequencies.

It is expected that the more complete report of the work will appear in the February issue of the *Journal of Research of the National Bureau of Standards.*

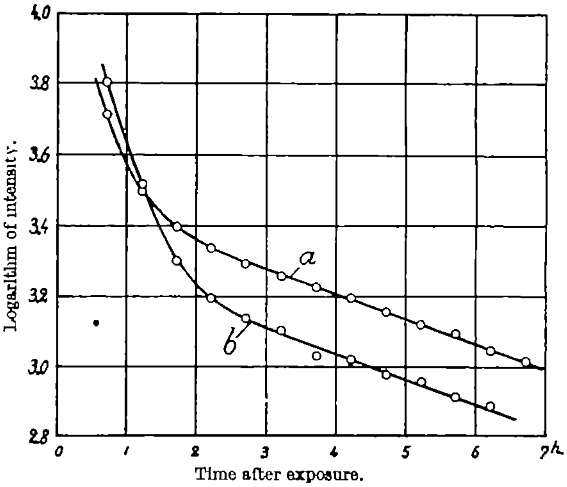
Isomeric Radio-Isotopes of Bromine

THE number of different radio-isotopes seems in several cases greater than can be explained by attributing to each of them a different mass-number. In particular, bromine irradiated with neutrons, γ-rays and deuterons gives four radio-isotopes (T = 7 min., 18 min., 250 min. and about 36 h.); and it seems that two of them, namely, the isotopes with T = 18 min. and T = 250 min., must have the same mass-number 80[1]). These facts, together with some others, have led several authors to assume the existence of isomeric nuclei.

Fleischmann[2] has recently investigated whether in the process (n, γ) the ratio of the two isomeric forms of ^{80}Br depends on the impinging neutron energy. He found that the resonance neutrons responsible for the formation of both isomers have the same absorption coefficient in boron, and concluded that the resonance levels of the compound nucleus leading to the two forms of ^{80}Br are identical. The ratio of equilibrium quantities of ^{80}Br (18 min.) and ^{80}Br (250 min.) is about 2·3 both for thermal and resonance neutrons.

As in this case the radio-isotopes are formed by neutron capture, it seemed to us of interest to investigate whether this ratio remains the same when the radioactivity is excited by the process (n, 2n), that is, when the collision of a nucleus with a fast neutron results in the expulsion of two neutrons. In consequence we have irradiated bromine (*a*) with fast neutrons having energies up to 14 × 10⁶ ev. produced by bombarding lithium with deuterons of 350 ekv., (*b*) with neutrons slowed down in a hydrogenated medium and originating from the same source or, alternatively, from a radon plus beryllium source. In both cases, the times of exposure and conditions of measurements were identical. During the runs the intensity and the voltage of the bombarding deuteron current were kept practically constant.

Bromine was exposed in the form of element; the irradiated bromine was transferred into a thin-walled glass vessel having the form of a cylindrical Dewar flask of 16 mm. inner diameter, which was put directly on a Geiger-Müller counter having brass walls of 0·05 mm. thickness. The activity was followed during 7 hours in order to determine exactly the ratio of the two isomers. It may be mentioned that in case (*a*) the activity obtained with a bombarding deuteron current of about 300 microamp. was so large that counting could be started only when the 7 min. product has practically decayed (about half an hour after the end of the exposure). The ratio of the initial number of impulses due to the two isomers and calculated for an infinitely long exposure was found in case (*a*) (process n, 2n) equal to 0·56 and in case (*b*) (process n, γ) equal to about 2. Fleischmann has obtained a slightly higher value in this last case, but it must be remembered that the exact experimental value depends on the conditions of absorption of the two kinds of β-rays in the particular arrangement used, if their energy distributions are different.



DECAY CURVES OF ^{80}BR OBTAINED WITH (*a*) FAST NEUTRONS AND WITH (*b*) SLOW NEUTRONS.

The logarithmic decay curves relative to the two cases are represented in the accompanying graph. It can be seen that initially the activity of radio-bromine formed by fast neutrons is smaller than the activity due to slow neutrons; on the other hand, it is much larger on the subsequent part of the curves.

Process (*a*) consists in the expulsion of two neutrons from the excited compound nucleus, while in process (*b*) we have to do only with a γ-radiation. It would be of interest to see whether an intermediate value of the ratio Br (18 min.) : Br (250 min.) is obtained when the radio-isotopes are formed with expulsion of one neutron, that is, by irradiation with hard γ-rays.

Formation of Lipin Phosphorus in Normal and Rachitic Rats, with a Radioactive Phosphorus Isotope as an Indicator

IN previous papers[1,2] we communicated the results of some experiments on phosphorus metabolism in normal, rachitic, and rachitic rats treated with vitamin D, by which the distribution, absorption and re-excretion in relation to the deposition in bone of the active phosphorus administered were examined.

Significant differences between the three groups of rats could not be established. A very rapid entrance of the 'labelled' phosphorus into the bone was perceptible in all cases. Furthermore, it was observed that one hour after the injection into the tail vein, a considerable amount of the radioactive phosphorus was re-excreted into the small intestine, whereas the phosphorus within one hour had disappeared entirely from the blood in several rats.

We have now investigated the formation of lipin phosphorus after injection of inorganic phosphorus in six normal and rachitic rats. The 'labelled' phosphorus was administered as sodium phosphate in an aqueous solution of pH 6·4. For that purpose a fixed quantity of the radioactive solution was injected into the tail vein. A certain time after the injection of the active sodium phosphate—in this experiment after ½ and after 2 hours—the rats were decapitated and the blood was caught in a tared cup. The body and the head were immediately plunged into liquid air, then pulverized and kept in a frozen condition in solid carbon dioxide, until the chemical estimations were done and the preparations for the determination of the radioactivity were made.

The radioactivity was measured with an ionization chamber[2] in four preparations of each animal, namely, the blood, the total-phosphorus fraction, the lipin-phosphorus fraction and the remaining phosphorus fraction. In addition, the total phosphorus, the lipin phosphorus and the remaining phosphorus content of the whole rats were chemically estimated. The results of the determination of the radioactivity proved that almost the whole of the active phosphorus injected could be recovered. The figures for the radioactivity of the several phosphorus fractions, however, showed a large variation, so that a significant difference between the normal and rachitic rats could not be established.

We found, however, two facts of importance, which will be discussed in this letter; namely, the low radioactivity of the blood and the rapid formation of lipin phosphorus from the inorganic phosphorus of sodium phosphate.

In the first place, the blood figures confirmed our previous results; it was found that both within half an hour and two hours after the injection, the active phosphorus for the most part had disappeared from the blood. At most, 16 per cent of the injected phosphorus was still present in the whole blood.

A second interesting and unexpected fact was observed concerning the formation of lipin phosphorus. In earlier investigations, Artom[3] and his collaborators had shown that about nine hours after the ingestion of fat and radioactive phosphorus, comparatively large quantities of the active phosphorus were already found in the phospholipins of liver and gut of a rat. Hahn and Hevesy[4] showed that, in one hour after the subcutaneous injection of labelled sodium phosphate, labelled lecithin was already formed in the brain tissue of a fully grown rat. Now we were able to establish that both in normal and rachitic rats, within half an hour after the injection of the active phosphorus, a large amount was present in the phospholipins of the whole animal. Sometimes about 30 per cent of the active phosphorus injected was determined in the lipin phosphorus fraction.

Therefore, it is obvious that the formation of lipin phosphorus from inorganic phosphorus proceeds very rapidly. Whether this process is a real esterification by which the lipins are constantly broken down and rebuilt again under enzymatic action, or the process is only an exchange of organic phosphorus atoms of the lipins for inorganic phosphorus atoms of the sodium phosphate, must be left here undecided. We purpose to examine this question later. Though a detailed account of these and further experiments will be published elsewhere, we direct attention to the accompanying table, which proves the large individual variation in the figures for the blood and for the lipid fraction of the whole animal.

Rat	Interval after injection	Percentage of active phosphorus injected, found in:	
		Whole blood	Lipid fraction whole animal
	h. m.		
normal	0 30	0	27·5
normal	0 30	0	6·5
normal	0 30	15·5	11·2
rachitic	0 30	6·5	3·5
rachitic	0 30	10	14
rachitic	0 30	9·8	11·6
normal	2	0	24·5
normal	2	2·7	0
normal	2	8·3	10·5
rachitic	2	8	3·5
rachitic	2	15·2	5·5
rachitic	2	16·4	16

In our opinion, therefore, it is necessary to use a sufficiently large number of rats in each experiment.

Finally, we wish to express our thanks to Mr. J. C. de Back, Mr. J. Bouman, Mr. W. F. van Schalkwijk and Mr. G. J. van der Maas for their valuable assistance in this experiment.

British Fisheries, Phosphate and the Solar Radiation Constant

IN the autumn of 1921 there was a remarkable movement of water in the Atlantic, northwards and into the English Channel. This persisted into the early winter, and water temperature rose, though air and ground temperatures were falling[1]. No explanation has been given for this occurrence, nor has it happened since then to the same extent.

In 1923 the phosphate content of the water of the English Channel was determined, and it was shown that, late in the spring, this constituent became exhausted in the surface water, while the deeper water was much depleted. Lack of phosphate therefore limits the multiplication of the phytoplankton and so of animals also. In winter, when light is deficient, much phosphate is set free again. Such measurements were repeated for several years, and my analyses have been continued by Dr. L. H. N. Cooper. Since 1923, there has been a decrease in the winter phosphate maximum, with minor irregularities. At the start the concentration was 20 per cent above the average and in the 1934–35 winter it was 26 per cent below it.

It has been shown by Russell[2] that the young of summer-spawning fish show a great decrease over this period, and though the young of the spring-spawning fish began to decrease later, their decrease is now even more pronounced.

The shortage of fish can only be made good when our coastal waters again become enriched by phosphate; this depends upon the influx of water enriched by the mixing of deep Atlantic water over the continental shelf.

The explanation of the movement of such large masses of warmed water, moving apparently because they have been warmed more than usual, is one that postulates a great supply of energy. When going through the results of Dr. C. G. Abbot[3] of the Smithsonian Institution, the remarkable maximum in the solar content during the autumn of 1921, as shown by his curves, at once offered what appeared to be a rational explanation. These solar variations are made up of a number of cycles differing in period and intensity, and I am indebted to Dr. Abbot[4] for the information "that the solar radiation has not since 1920 and 1921 been so high for any considerable time as it was in those years. Nor has there been any such great fall in the solar constant as that of 1922". The fluctuation of individual days may show a range of 8 per cent[5], but more usually fluctuations are nearer 2 per cent. Terrestrial effects have been traced with still smaller variations.

The revised value[6] for the solar content of radiation is 1·933 calories (15° C.) per cm.^{2} per minute; this is the value outside the earth's atmosphere. The amount of heat reaching the surface of the ocean depends also on the absorption of the atmosphere, which on a large scale is itself dependent upon the amount of water which has been evaporated. The changes in the solar constant are only small percentages, but even small percentage changes may conceivably produce very large effects since the energy involved is so great.

In conclusion, it may be said that, while the relation between phosphate concentration and the abundance of the plankton each year is well established, the connexion between the abnormal movements of large masses of water and the solar constant of radiation is a reasonable speculation which is capable of being tested further in the future.

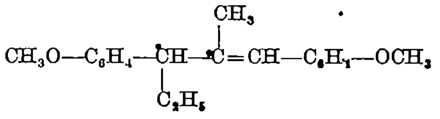
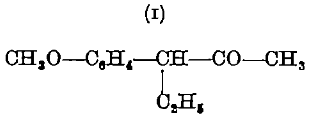
Œstrogenic Activity of Di-Anol, a Dimeride of *p*-Propenyl-Phenol

DI-ANETHOLE or iso-anethole (I) has been described by Kraut and Schlun[1] and later by Orndorff, Terrasse and Morton[2] as an unsaturated liquid dimeride of anethole. Its structure was established by Goodall and Haworth[3], who obtained from it, by oxidation, anisic acid and a ketone, which was identified as (II) by synthesis.



$$CH_3O—C_6H_4—\underset{\displaystyle C_2H_5}{CH}—\overset{\displaystyle CH_3}{C}=CH—C_6H_4—OCH_3$$

(I)



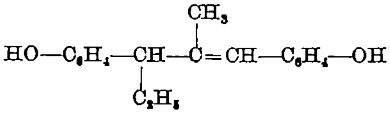
$$CH_3O—C_6H_4—\underset{\displaystyle C_2H_5}{CH}—CO—CH_3$$

(II)

This di-anethole has œstrogenic properties, doses of 100 mgm. producing œstrus in three out of five castrated female rats. Demethylation was effected by heating with 2 parts potassium hydroxide and 4 parts alcohol at 190–200° C. for 16 hours. The product is a dark brown gum which is fully active in doses of 0·1 mgm. This crude product was boiled with acetic anhydride and the crude acetate distilled at 277–280° at 23 mm. and gave on analysis: C, 75·0; H, 6·9 per cent ($C_{22}H_{24}O_4$ requires: C, 75·0; H, 6·9 per cent).

The free phenol was recovered by hydrolysis and distilled at 264–266° at 20 mm. This was a pale yellow gum which darkened in contact with air. (Found: C, 79·6; H, 7·5 per cent; $C_{18}H_{20}O_2$ requires: C, 80·55; H, 7·5 per cent.)

This product, *di-anol*, in 100γ doses produced œstrus in 100 per cent of rats used, while 50γ doses gave a 60 per cent response. The acetate, which is perfectly stable in air, is fully active in doses of 200γ. No crystalline derivative has so far been prepared. The structure of this phenolic gum was shown to be (III) by methylation, and identification of the product as di-anethole (I). The dimethyl ether was oxidized by the method of Goodall and Haworth, yielding anisic acid and the ketone II.



$$HO—C_6H_4—\underset{\displaystyle C_2H_5}{CH}—\overset{\displaystyle CH_3}{C}=CH—C_6H_4—OH$$

(III)

An investigation is being made into the possible occurrence of this substance among the phenolic by-products produced from the preparation of anol (*p*-propenyl phenol)[4,5] by demethylating anethole with alcoholic potassium hydroxide at 200°.

Adrenal Cortex Differences in Male and Female Mice

THE sex difference in the adrenal cortex of mice, first described by Masui and Tamura[1] and later studied histologically and experimentally by Howard-Miller[2] and by Deanesly[3], has since been the subject of a number of publications[4,5,6]. Various far-reaching theories have been put forward, in spite of the fact that no other species so far studied shows the same histological distinction between male and female adrenals.

The essential difference, which can be first traced at the age of about five weeks, consists in the much greater development of the inner cortical zone in the young female mouse. Howard-Miller[2] introduced the term 'X-zone' for this region of small, darkly staining, lipoid-free cells, to distinguish it from the zona reticularis common to males and older females, which is smaller in area and less sharply delimited from the rest of the cortex (Deanesly[3], Fig. 2–5). It was found that the X-zone degenerated rapidly in the middle of the first pregnancy and more gradually with age in the non-parous female. Its growth and degeneration are unaffected by ovariectomy. Castration, however, causes a well-developed X-zone to arise, concurrently with the enlargement of the adrenal, but this, like the X-zone of the female, gradually degenerates in older castrated animals.[7] Cramer[4], for reasons not found convincing by other workers[8], describes this transient zone as part of the medulla and not as part of the cortex.

It has now been shown[9,10] that the castration change in mouse adrenals can be readily inhibited or abolished by injections of androgenic extracts of urine or various synthetic male hormones, even of *trans*-androstenediol in amounts inadequate to cause growth of the seminal vesicles. These results support the view that the difference in the adrenals of the two sexes is entirely controlled by the secretions of the gonads.

On the other hand, a recent study of pituitary-deficient dwarf mice from a well-known genetic strain tends to throw doubt on this theory. The dwarfs, described by Smith and MacDowell[11] and Kemp and Marx[12], are homozygous for the recessive dwarfing factor and cease to grow at about 7·5 gm.; their adrenals, though small, are normal in appearance. Examination showed, however, that they are of the male type in both sexes, that is, the X-zone fails to develop in the female at any age, and the zona reticularis is restricted to a narrow band round the medulla. In view of this finding, the effects of castration on the dwarf mice were also investigated. Four male dwarfs aged 2–5 months were castrated and killed 15, 25, 30 and 42 days after castration. Slight enlargement of the adrenals were found, but no X-zone arose, although in the normal mouse this is well developed at four weeks after castration.

The absence of the X-zone suggests strongly that it is dependent on some secretion of the pituitary in which the dwarf mice are deficient, but the condition of their reproductive organs makes it unlikely that the gonadotrophic hormone is involved. As Smith and MacDowell[11] have pointed out, the gonads and accessory organs are by no means infantile in the dwarf mice, particularly in the males; spermatozoa may be formed in the testes, and the seminal vesicles undergo appreciable development. After castration, the latter show typical shrinkage.

The X-zone, as suggested in earlier work[3], seems to be essentially connected with adrenal growth, since it develops when the whole cortex is growing actively, as, for example, in normal prepubertal females, or in males after castration, especially after prepubertal castration. It is a transitory hyperdevelopment of the inner cortex comparable to the zone which degenerates in the human adrenal after birth[2,3]. The fact that it regresses under the direct or indirect influence of male hormones provides no evidence in support of the theory advanced by Grollman[5] and Howard[6] that the X-zone is particularly associated with the known androgenic activity of the adrenal[13,14].

I am indebted to Dr. H. Grüneberg, Department of Genetics, University College, London, for a supply of the dwarf mice.

Electric Impedance of Marine Egg Membranes

ALTERNATING current impedance measurements were made during the past summer on unfertilized and fertilized *Arbacia punctulata* eggs to determine whether or not an interpretation which has been given[1,2] for the low-frequency increase of capacity on fertilization is correct. The earlier data on *Hipponoe*[3] (*Tripneustes*) *esculentus* and *Arbacia*[1] egg suspensions showed the presence of two capacity elements, and it was suggested that the plasma membrane capacities of about 0·8 μf./cm.^{2} remained unchanged on fertilization and that the fertilization membranes appeared with capacities of about 2 and 3 μf./cm.^{2} respectively. The capacity element of the fertilized egg suspensions which was attributed to the plasma membrane has been much less pronounced in the recent measurements on both suspensions[4] and single eggs[5], and it has also been found, for both unfertilized and fertilized eggs, that the relatively non-conducting membrane lies either at or very close to the plasma membrane. Thus the increase in capacity on fertilization is probably due entirely to a change in the plasma membrane. It is possible that the second capacity element shown by the older measurements was due to unfertilized eggs in the fertilized suspensions.

Delayed Mitosis and Chromatid Fusion

INVESTIGATIONS have been made with the seeds of several plants on the production of chromosome mutations through ageing[1,2]. With such material it is difficult, if not impossible, to separate the primary changes from any secondary ones which may follow them. It is, in fact, these primary changes which are of extreme importance for any theory of structural change.

The pollen of many plants is viable over long periods and the time of the pollen-tube (second post-meiotic) mitosis can be controlled directly by the time of germination. I have made an investigation of the changes induced by ageing on the pollen of *Pæonia Veitchii* ($n=5$) and *Kniphofia rufa* ($n=6$). The mature pollen was collected and stored at laboratory temperatures in a desiccator over anhydrous calcium chloride and germinated after varying intervals on Knop-sucrose solution to obtain the pollen-tube division. There was little, if any, decrease in the percentage germination over the period of the experiment.

I find evidence of a new kind of structural change in old pollen. Numerous chromatid bridges occur in cells without fragments. Fig. 1 illustrates the type of the changes. I observed only two instances of fragmentation in cells without bridges. There is a lag phase of two to three weeks before the changes begin to occur with appreciable frequency. A curve of bridge formation with time is given in Fig. 2 for *Kniphofia rufa*. The frequency distribution of the bridges, 0, 1, 2 or 3, in the individual nuclei of any one set of observations is very close to the binomial expected on random formation. There is thus no interference within the nucleus between bridge production in the separate chromosomes or chromosome arms. No interlocked types or other configurations which could only have been derived from two chromosomes, as Husted[3] noticed after X-ray breakage, have been found. We can only suppose that the bridges originate by union of the homologous ends of the two sister chromatids derived by division from one parent chromosome. The same conclusion was reached by Upcott[4] from observations of similar bridges in the first post-meiotic mitosis in the immature pollen grain.

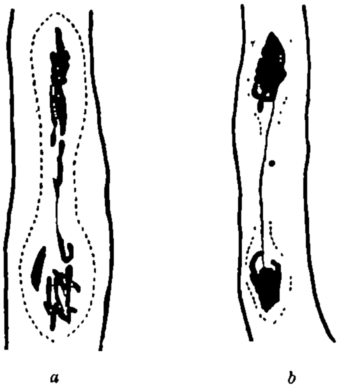

Fig. 1.

a: BRIDGE IN SHORT ARM OF CHROMOSOME IN 7 WEEKS OLD POLLEN OF *Kniphofia rufa*. THE BODY TO THE LEFT OF THE LOWER ANAPHASE GROUP IS A PERSISTENT NUCLEOLUS. ×1200. *b*: SINGLE BRIDGE IN 3 WEEKS OLD POLLEN OF *Pæonia Veitchii*. ×1200.

These findings reopen the questions which have been much discussed in the mechanics of structural change, as to the possibility of the union of chromosome ends and of the existence of a definite 'end-body' to the chromosome preventing such union[5]. They suggest that the changes produced by age may obey different rules from those produced by X-ray treatment. Any general theory of structural change must take into account these differences.

Osmosis in Physics and Biology

A MIXTURE was prepared containing lecithin and cholesterin (and beeswax) in a solution of ether; this mixture was imbibed (by vacuum) in the pores of a clay cylinder. This was dried and then filled with a molal solution of cane sugar and put in the same liquid; the solution was heated inside by an electric current and cooled outside by a water supply.

Water came out from the heated region against a pressure of 70 mm. mercury. This seems to offer an explanation of the mobilization of a liquid by living cells against the concentration gradient, and shows a possibility of using heat as a direct source of energy.

Does Iron occur in the Solar Corona?

STRATTON[1] was able to recognize two 'forbidden' N II-lines in the beautiful photographs of the corona spectrum obtained by Sekiguti[1] at the total solar eclipse of June 19, 1936, and so to prove the occurrence of nitrogen in the solar corona. Moreover, Sekiguti noticed that two of the corona lines, λ 4815·9 and λ 5738·0, on his photographs came very close to the nebular lines λ 4814·78 and λ 5737 in the spectrum of η-Carinæ. One of these two lines (λ 4814·78) is amongst those which Merrill[2] recognized as 'forbidden' Fe II-lines. Should this identification be the correct one, this would mean that in addition to nitrogen another element, namely, iron, exists in the solar corona. In view of the interest generally taken in the chemical composition of the solar corona, we wish to discuss in some detail the possibility of such an identification.

It is strongly supported by the circumstance that λ 4814·78 is the strongest line of the multiplet to which it belongs. This is shown by the empirical evidence from the spectrum of η-Carinæ[2], which is supported by the following consideration: λ 4814·78 is due to the transition $3d^6\ (^3F)\ 4s\ ^4F_{4\frac{1}{2}} \rightarrow 3d^7\ ^4F_{4\frac{1}{2}}$, and is to be considered as an electric-quadrupole line. In the case of pure Russell-Saunders coupling, magnetic-dipole transitions occur exclusively between the fine structure components (levels) of an energy-term. Only if we take spin-orbit interaction into account (that is, at the same approximation at which intercombination lines appear) are magnetic-dipole transitions between the terms of the same electron configuration possible. As we are dealing in this case with a transition between two different electron configurations, it is only configuration interaction which can cause magnetic-dipole radiation. This, however, will be presumably negligibly small in comparison with electric-quadrupole radiation obtained already in zero order approximation. We can thus make use of the intensity formulæ for electric-quadrupole radiation in the case of pure Russell-Saunders coupling, which confirms the correctness of our statement that λ 4814·78 is the strongest line of the whole multiplet[3]. The intensity of the other lines of this multiplet is always less than about 40 per cent of the intensity of the line considered. As this is one of the faintest in the corona spectrum, the remaining lines of this multiplet can obviously not be visible on Sekiguti's photographs.

A very serious objection, however, against considering λ 4815·9 as a Fe II-line is the impossibility of tracing any other iron line in the corona spectrum, particularly those, the initial term of which is the same as that of λ 4814·78; for example, the intercombination line λ 4416·28, which is in the η-Carinæ spectrum nearly twice (9 : 4) as strong as λ 4814·78. Thus it is not quite justifiable to identify the corona line λ 4815·9 with λ 4814·78 in the spectrum of η-Carinæ unless additional evidence is obtained.

A. RUBINOWICZ.

Institute of Theoretical Physics,
John Casimir University,
Lwów. Nov. 19.

[1] NATURE, 140, 724 (1937).

[2] *Astrophys. J.*, 67, 391 (1928).

[3] Bowen, I. S., *Rev. Mod. Phys*, 8, 35 (1936).

PROF. RUBINOWICZ has somewhat overstated my point of view in suggesting that a provisional identification of two forbidden lines of N II in the coronal spectrum proved the occurrence of nitrogen in the corona. He carefully safeguards himself from any claim that a suggested identification of one forbidden line of Fe II proves the presence of iron. But the case for iron is actually stronger than he has stated. The missing line, λ 4416·28, to which he refers, is a forbidden transition between two levels in the same electronic configuration; and a search by Dr. Dobbie and myself of the more likely transitions of this class, which might give lines in the region of spectrum available for study, has indeed failed to show any coronal lines. On the other hand, Prof. Tanaka's list of coronal lines[1] does show coincidences with two forbidden Fe II lines, λ 4244·0, $a\ ^4F_{4\frac{1}{2}} - a\ ^4G_{5\frac{1}{2}}$, and λ 5072·4, $a\ ^4F_{4\frac{1}{2}} - a\ ^4H_{4\frac{1}{2}}$, these lines, like Prof. Sekiguti's line λ 4814·5, $a\,^4F_{4\frac{1}{2}} - b\,^4F_{4\frac{1}{2}}$, all represent transitions from levels in the d^6s configuration to the lowest level of the d^7 configuration. The suggestion is that the conditions at this eclipse were favourable for the emission of forbidden lines of Fe II caused by transitions between two different electronic configurations; in such cases the transition probabilities for electric quadrupole radiation would be much higher than for magnetic dipole radiation.

The reality of faint lines observed but once in a coronal spectrum must remain uncertain. The stronger coronal lines, however, vary so much from eclipse to eclipse and from point to point in the corona that the very weak lines may well be irregularly present or absent. This provisional identification of forbidden lines does not touch the main corona spectrum but may serve as a pointer towards its ultimate identification.

Adsorption of Constituents of a Solid Phase on the Surface

IT is a well-known fact that the concentration of alloying elements in the scale formed on heating an alloy in air differs in most cases considerably from the average composition of the material. The product of high-temperature oxidation of brass, for example, consists of zinc oxide only. At lower temperatures cuprous oxide is the prevailing constituent[1]. Iitaka and Miyake found nothing but BeO on the surface of copper-beryllium alloys containing so little as 1 per cent of beryllium. Copper-aluminium alloys with several per cent aluminium content, heated with a Bunsen burner, gave Al_2O_3 in places which had been embedded in the flame, while CuO was found on those parts of the surface which had been in contact with air[2].

Attempts at explaining these rather complicated phenomena were based chiefly on chemical arguments. The absence of copper oxide on brass, for example, was attributed to the reduction of cuprous oxide by zinc. Although the importance of secondary chemical reactions in some special cases can scarcely be contested, the accumulation of a constituent of an alloy on the surface can be explained in a quite general manner on a purely physical basis.

It was anticipated by J. W. Gibbs and J. J. Thomson and proved experimentally, that the tendency to reduce the free surface energy of a solution to a minimum results in concentration of the constituent with the smallest surface tension on the surface[3]. Although there were *liquid* solutions which were concerned in these investigations, there is nothing in the argument which would prevent applying the conclusion to the state of equilibrium of a *solid* phase. If, following Desch[4], we assume as a tentative hypothesis that the values of the surface tension of solid metals are roughly proportional to those for the liquid state in the neighbourhood of the freezing point, we can arrange metals according to their surface tension in a following series :

Sb, Bi, Pb, Hg, Sn, Cd, Zn, Ag, Au, Cu ;

the surface tension of antimony being the smallest, that of copper the greatest. As to the surface tension of other metals, no data are available. In any alloy the constituent preceding the others in this series should tend to accumulate on the surface. As the surface tension of metals is higher than that of any compound or non-metallic element, non-metallic constituents should also show a tendency to displace the metal from the surface. At ordinary temperatures the rate of diffusion is so small that it would take a very long time to reach the state of equilibrium ; it is only when the diffusion is accelerated by high temperature or loosening the crystal texture by alternating stresses or polishing, that the effect is brought into prominence. The conclusion was confirmed by the following experiments :

A copper specimen containing 0·01 per cent of sulphur, etched in nitric acid, which had given the normal copper pattern on electron diffraction examination, was kept *in vacuo* for 4 hours at 800° C. After this treatment the covelline copper sulphide pattern has been obtained without any trace of copper rings. It shows that all the metallic copper has been displaced from the surface down to the depth of several tenths of an angstrom at least.

An etched bar from the same material was clamped in a lathe and rotated rapidly, while the free end was loaded. It was cooled all the time to prevent oxidation. On examination of a specimen cut from the part next to the chuck, it is found that copper sulphide has been formed on the surface.

A specimen burnished under benzene with an agate burnisher gave also the copper sulphide pattern. When using copper with 0·005 per cent sulphur content, copper sulphide rings were still clearly visible. Pure re-melted copper treated in a similar way yielded the usual diffuse pattern of polished copper.

A 98 per cent copper 2 per cent beryllium alloy burnished under benzene gave diffuse haloes, the spacings of which, 1·86 A. and 1·11 A., correspond, according to Prins's formula, to the size of beryllium atoms[5]. It points to the existence of a pure beryllium layer on the surface.

A 71/29 brass burnished under benzene and dipped afterwards in ammonium sulphide solution gave the wurzite zinc sulphide pattern. Apparently there is a thin layer of pure zinc on a polished brass surface.

These results throw fresh light on the problems of corrosion resistance of alloys, especially at high temperatures. Adsorption on the surface explains the protective action exercised by some constituents even if present in quite small quantities. An improvement which polishing produces in the corrosion-resisting properties of some stainless steels with low nickel content may be also interpreted from this point of view. The problem of bearing alloys is another field where this phenomenon may be expected to take an important role.

A more detailed account will be published in *Bull. Int. de l'Acad. Polonaise de Sci. et Lettres.*

Viscosity of Air

RECENT determinations of the viscosity of air by Bond[1] (capillary tube method) and Kellstrom[2] (rotating cylinder) have yielded a value

$$\eta_{23^\circ \text{ C.}} = (1834{\cdot}8 \times 10^{-7}) \text{ C.G.S.}$$

Substituted in Millikan's data on the determination of e, this value gives

$$e = 4{\cdot}817 \times 10^{-10} \text{ E.S.U.},$$

which is considerably higher than values of e obtained by other methods.

In conjunction with Dr. Bond, I commenced a fresh determination with several improvements in the apparatus. As a result of a large number of experiments on three different sets of tubes, I find

$$\eta_{17^\circ \text{ C}} = (1800{\cdot}8 \pm 0{\cdot}7) \times 10^{-7} \text{ C.G.S.}$$

My experimental value of the temperature coefficient is $4{\cdot}93 \times 10^{-7}$ per ° C., agreeing with the value found by Millikan[3]. Thus I obtain

$$\eta_{23^\circ \text{ C.}} = (1830{\cdot}3 \pm 0{\cdot}7) \times 10^{-7} \text{ C.G.S.}$$

If this value is substituted in Millikan's oil drop data, the result is

$$e = (4{\cdot}800 \pm 0{\cdot}004) \times 10^{-10} \text{ E.S.U.},$$

which is in very good agreement with the value of e deduced by von Friesen[4] from recent values by X-ray and electron diffraction methods.

Pyrrolidone: a Chemical Group of Particular Significance to Differentiation

THE inquiry into whether or not the naturally occurring tissue components of general distribution play a part in developmental growth has brought out that each amino-acid and nucleic acid derivative has its own separate and peculiar effect upon the growth of *Obelia geniculata*[1].

Although the individuality is indubitable, certain compounds produce a like effect on differentiation expression when they are present singly in the culture solutions. Nicely enough, it is possible to trace a chemical relationship between these differentiation-forwarding substances other than the simple fact that they are composed of carbon, nitrogen, hydrogen and oxygen.

The differentiation-enhancing compounds are first, *d*-glutamic acid and its homologue *l*-aspartic, *l*-proline and *l*-hydroxyproline. The members of this group are interconvertible through pyrrolidone carboxylic acid, a common intermediary[2,3]. Then there is tyrosine, from which melanin is formed by tyrosinase through compounds identified as carrying the benzopyrrole ring[4]. Finally, differentiation is advanced by cytosine and thymine, two nucleic acid derivatives which carry the carbonyl-imid-methine sequence in heterocyclic configuration similar to pyrrolidone[5].

$$\underset{O}{C}-\underset{H}{N}-\underset{H}{C}$$

It is clear that the group of differentiation-forwarding compounds is united by the common possession of a potentiality for yielding a single and unique type of chemical configuration. The association is too close-knit to be fortuitous.

The assumption is therefore justified that in the pyrrolidone configuration or some part or derivative thereof is to be found that chemical constellation which is a specific determinant and participant in some phase of that chemical specialization which is differentiation, and through which cells are brought to their characterizing functionable and structural maturity.

The possible significance of this to neoplasia is clear—for through the application of the principle it is possible that cancer cells may be brought to maturity—if they can be so brought—and thus the lethal aspects of this growth be diverted. Work in this direction will be carried out.

Points from Foregoing Letters

DR. P. KAPITZA describes new experiments from which he deduces that the viscosity of helium II (below the λ-point) is at least 1,500 times more than that of helium I at normal pressure, which may account for the abnormally high heat conductivity of helium II. He suggests that helium, below the λ-point, enters a special state that may be called super fluid. Further experiments are reported by J. F. Allen and A. D. Misener indicating that the flow of helium II at 1° K. does not follow the ordinary equation for laminar or turbulent motion. The authors consider that the type of motion observed might arise from slipping of helium II over the surface of the tube, in which case the flow method would not be likely to give a value of the viscosity which had much meaning, and that undamped turbulent motion cannot account for an appreciable part of the high thermal conductivity observed.

The potential difference between the end of a tin wire at the transition temperature (of supraconductivity) according to Dr. F. B. Silsbee, Dr. F. G. Brickwedde and R. B. Scott, contains a component of double the frequency of the alternating current (200 kc./sec.), when the last-mentioned is superposed upon a direct current, so that the resulting magnetic field at the surface of the wire is caused to pulsate cyclically.

Prof. A. Sołtan and Prof. L. Wertenstein have found that the ratio of formation of the two radio-isotopes of bromine with half-lives 18 min. and 250 min. which, according to recent views, are considered as representing two isomeric forms of the nucleus ^{80}Br, is distinctly different when the radioactivity is excited with fast (up to 14×10^6 ev.) and slow (thermal and resonance) neutrons. This ratio is equal in the first case to 0·56 and in the second case to 2.

By injecting 'labelled' sodium phosphate into the tail vein of six normal and six rachitic rats, Dr. M. J. L. Dols and Prof. B. C. P. Jansen, in collaboration with Prof. G. J. Sizoo and F. Barendregt found that within half an hour a considerable amount of the inorganic phosphorus injected had been transformed into organic phosphorus of lipins. The blood figures confirmed their previous results; within half an hour after the injection, the active phosphorus had, for the most part, disappeared from the blood. Significant differences between normal and rachitic rats could not be established.

From changes observed since 1923, Dr. W. R. G. Atkins points out that the relation between phosphate concentration and the abundance of plankton in the water of the English Channel is well established. He suggests that there is also a connexion between the abnormal movement of large masses of water from the Atlantic Ocean to the Channel and the change in the amount of radiation from the sun.

Miss Ruth Deanesly reports that castration of young male dwarf mice does not enlarge the '*X*-zone' of the adrenal, a region of small, darkly stained, lipoid-free cells, found in the adrenal cortex of normal female mice, and also developing in normal castrated mice, unless counteracted by injections of male sex hormone. The new experiments indicate that the development of the '*X*-zone' is not controlled solely by secretion of the gonads but may be dependent upon some secretion of the pituitary in which the dwarf males are deficient.

H. N. Barber reports that chromatid bridges are induced by ageing in the second postmeiotic mitosis of pollen of *Pæonia* and *Kniphofia* species. They are probably formed by union of the homologous ends of the sister chromatids derived by division from one parent chromosome.

Prof. A. Rubinowicz notices that Prof. Sekiguti's identification of the coronal line λ 4815·9 with the nebular line λ 4814·78 in the spectrum of η-Carinæ would indicate the occurrence of iron in the solar corona. Although this identification appears to be partially justifiable, certainly further evidence for its support is needed. Prof. F. J. M. Stratton also discusses this identification.

Dr. S. Dobinski finds that the concentration of alloying elements in the neighbourhood of the surface is governed by the surface tension of the constituents and differs in most cases considerably from the average composition of the material. Electron diffraction experiments on some copper alloys confirm this view.

Research Items

Effect of the Medium on Radium-sensitivity of Cells

IN a communication addressed to the Editor, Dr. G. Harker, of the Cancer Research Committee, University of Sydney, describes the extension of his observations (NATURE, 137, 190; 1936) on the inhibiting effect of radiation from radium plaques on the inversion of sucrose by living yeast cells, an effect now found also with X-radiation. If during irradiation with radium the cells are kept in suspension by gentle stirring, the inversion of sucrose is less than in the unstirred cells, although, owing to settling, the latter are much closer to the radium. The magnitude, and even the direction, of this effect are dependent on the neutral salt content of the medium. Since Loofbourow *et al.* (NATURE, 139, 589; 1937) have shown that stimulating substances may be liberated from irradiated cells, Dr. Harker removed the aqueous suspension fluid by centrifuging the suspension of cells after 18 hours irradiation by 30 mgm. of radium, and re-suspended the cells in fresh sucrose. It was found that the passage of substances from the cells into the liquid increased inversion in both this and the non-irradiated control specimen, but the increase was greater in the irradiated one. When the cells were irradiated in 10 per cent sucrose solution with the same quantity of radium, after 5 hours exposure the extent of inversion by the re-suspended yeast was less than that of the control; after 18 hours it was greater. It is concluded that in the early stages stimulating, and in the later stages inhibiting, substances are given off into the solution by irradiated yeast cells, and that the solution in contact with the cells plays an important part in these effects.

Anatomy of the Ox

WHILE a considerable amount of work has been done on the dog and horse, so that the anatomy of these animals is now fairly well known, not nearly so much has been done on cattle. In a recent publication, H. N. Chelva Ayyangar (Imp. Council Agri. Research, Sci. Monograph No. 11, 1937) has provided a detailed account of the course, constitution and distribution of the nerves supplying the levator anguli scapuli and rhomboideus muscles and of the formation of the phrenic nerve in the ox. In the same monograph are included descriptions of forty-seven deviations from the normal course or constitution of various arteries and nerves in the same animal. Thirty-seven of these have already appeared separately, but are here gathered together. The monograph is fully illustrated by seventy-one diagrams or photographs of the actual dissections.

Biology of Rhodesian Diptera

THE attention of students of Diptera is directed to two papers by Mr. Alexander Cuthbertson (*Proc. and Trans. Rhodesia Sci. Assoc.*, 35, August 1937). These articles deal with the biology of various Diptera inhabiting Rhodesia. In the first paper are given short accounts of the larva and pupa of *Solva* (Xylophagidæ) and of species of *Tabanus*, *Rhynchomyia* and *Tricylea*, which are also figured in the text. Three new species of Asilidæ are also described by Dr. E. O. Engel, of Munich, who collaborated with the author. In the second paper there are given biological notes and observations on various Diptera, including accounts of a number of species of Asilidæ and the prey which they had captured.

Sense Organs of Fishes

A CONDENSER-COUPLED five-stage amplifier, a Matthews's oscillograph, a loud-speaker and a delicate perfusion method were employed by A. Sand (*Proc. Roy. Soc.*, B, No. 833, Aug., 1937) to investigate the mechanism of the lateral sense organs of fishes. The types employed were the roach, the rudd, the plaice, the dogfish and three species of rays. The receptors of the lateral line system show a common mode of behaviour with those of the semicircular canals, which is perhaps not surprising when one takes into consideration the origin of the two sets of organs. Excitation is brought about by the movement of the fluid in the canal; that it is a fluid is demonstrated by the ease with which it can be utilized in perfusion. It is a system of great mechanical sensitivity and can appreciate tapping, made with a hammer on the table on which the specimen lies, that is too slight for perception with the hand. There is a spontaneous frequency of discharge from the individual end-organs, and a slow movement of the fluid in the canal produces a response over and above these. Over the greater portion of the range of stimulation the receptor organs obey the logarithmic law. The two directions of flow in the canal have contrary effects, that in one direction being excitatory and in the other inhibitory. The lateral-line sensory system is shown to be remarkably sensitive to low-frequency vibrations.

Polychætes from the Indian Ocean

THE Polychætes collected by the John Murray Expedition 1933–34 have yielded a high proportion of new forms. Mr. C. C. A. Monro, to whose care was allotted the task of describing the collection, has found it necessary to create one new genus, thirteen new species and four new varieties (John Murray Expedition 1933–34, Scientific Reports, 4, No. 8, Polychæta, 1937). Several of these came from deep water, whence, indeed, much of the collection came. Of the new species may be mentioned a *Nereis* with remarkably long pedal languets and a *Eunice* with extremely long and highly pectinate gills. Some of the species taken were previously known from localities in parts of the world far removed from the Indian Ocean. Thus from 1519 metres and below in the Arabian Sea comes a specimen of the Magellan *Goniada eximia* Ehlers, and from the Gulf of Aden at 91 metres an example of *Chætozone setosa* Malmgren, the single specimen being inseparable from one of the same species taken at Spitsbergen. This *Chætozone* had not previously been recorded from tropical seas. These and some other similar records again emphasize the cosmopolitan distribution of many Polychætes, and form one of the most valuable features of this excellent report.

Ecology of Soil Fungi

FACTORS which govern the numbers of soil fungi are of vital importance for the maintenance of continued fertility. Investigations into the effects of manurial treatment, season and crop upon the quantity and quality of soil micro-organisms have not been numerous, but Dr. Jagjiwan Singh has recently published the results of such a research problem (*Ann. App. Biol.*, 24, 1, 154–168, Feb. 1937). A direct correlation between soil fertility as measured by crop growth, and the number of fungi and Actinomycetes, has been established for two fields at the Rothamsted Experimental Station. Barn field, with permanent mangolds, and Broadbalk, with permanent wheat, are the two fields concerned. No dominant effect of the crop upon the soil micro-flora has been observed, nor can any effect of seasonal periodicity be claimed. Manurial treatments do not appear to induce specific fungal floras, though there was some evidence that *Penicillium* and *Dematium* species were more widely distributed in the Barn field, whilst *Fusarium* was most common in the permanent wheat land.

Long-range Weather Forecasting

SIR GILBERT WALKER has recently published an account of the methods adopted by the German Institute for Long-Range Weather Forecasting, under the directorship of F. Bauer, for its regular ten-day forecasts (*Quart. J. Roy. Meteorol. Soc.*, Oct. 1937). Statistical relationships connecting German weather with five-day means of pressure and temperature at distant centres of action are employed, also the method of studying the sequences of weather that followed the synoptic situations most resembling that of the forecast day; but apart from the thoroughness with which these parts of the work are done, there is nothing essentially novel about them. New ideas are, however, introduced in the conception of what may be translated as the 'broad-weather' situation—a condition of the atmosphere persisting for several days during which it controls the weather, being itself governed by conditions both in the troposphere and lower stratosphere. It has been found that the movements of regions of rising and falling surface pressure determined for a 24-hour interval, and defined by 24-hour isallobars, are usually almost completely in accordance with the gradient wind at a height of 5 km. and not with winds near the ground. At times, however, the 'steering' of the 24-hour isallobaric regions is by winds in the stratosphere, and that of the 3-hour isallobars by the winds of the lower troposphere. It has been found that the mean duration of a 'broad-weather' situation is 5½ days, and that their life-histories are closely connected with the formation and decay of 'highs' and 'lows' in the stratosphere. Since isallobaric systems most often move from some westerly point, this method would be less effective in British forecasting, where identification of the systems is hampered by paucity of observations to westward.

Rare Gases from the Hot Springs of Bath

OLDER examinations of the gases from Bath Springs had shown that these contained helium, argon and neon. The helium could be attributed to radioactive change and the argon might be derived from the atmosphere, but the reported presence of a large proportion of neon was unexplained, since this gas is less soluble than argon in water. M. W. Travers (*J. Chem. Soc.*, 1561 ; 1937) has analysed the gases from the King's Well and the Cross Spring and finds that the rare-gas fraction in each case consists of argon with about 12 per cent of helium and only 0·1 per cent of neon. The helium is certainly the product of radioactive change ; the argon and neon are probably of atmospheric origin, the neon content being about half that in the atmosphere on account of its lower solubility. The gases from the springs were found to be free from oxygen but contained carbon dioxide ; they contained about 13 c.c. of rare gas per litre. The rare gases were separated by means of fractionation by cooling.

Gypsum and Anhydrite

THE important transition temperature of gypsum and anhydrite : $CaSO_4, 2H_2O \rightleftharpoons CaSO_4 + 2H_2O$, was given as 63·5° by van't Hoff and his co-workers and has been generally accepted. Very different temperatures have been reported by later experimenters. A. E. Hill (*J. Amer. Chem. Soc.*, 59, 2242 ; 1937) has made a careful revision of this matter, particular attention being given to the attainment of equilibrium. It was known that anhydrite solutions could remain unsaturated or supersaturated for months, and hence an attempt was made to reach equilibrium from both directions, at 65°, 45° and 35°. From the solubility curves and previous data, it was found that a solubility curve could be drawn between the temperatures of 20° and 100° which was found to cut the well-authenticated curve for gypsum at 42°, which is the transition temperature. It will be seen that the new figure is about 20° lower than van't Hoff's figure of 63·5–66°. The usual difficulty of reaching equilibrium from the side of supersaturation was encountered.

Glide in Crystals

PROF. ANDRADE and his school are carrying out extensive work on the glide phenomena in strained single crystals. E. N. da C. Andrade and L. C. Tsien (*Proc. Roy. Soc.*, A, 163, 1 ; 1937) have investigated slip in single crystals of sodium and potassium which belong to the body centred cubic system. Work on other metals which crystallize in this system shows that glide usually takes place in the [111] direction, but that the glide plane is not, as it generally is in other structures, the most closely packed plane. The sodium and potassium crystals were formed by cooling a tube of the molten metal progressively from one end, and were stretched under paraffin oil. The slip markings on the surface of the crystal were correlated with X-ray Laue diagrams of the crystal structure. The direction of glide was always very close to a [111] direction. The glide plane was (123) in these experiments, in which the angle between the axis of the wire and the 123 plane lay between 30° and 50°. Single crystals of molybdenum were prepared by a method in which a region of high temperature gradient was made to travel along a wire which was maintained at a high temperature (Andrade, *Proc. Roy. Soc.*, A, 163, 16 ; 1937). The structure is body centred cubic, and experiments on the glide phenomena (L. C. Tsien and Y. S. Chow, *Proc. Roy. Soc.*, A, 163, 19 ; 1937) show that the glide direction is [111]. The glide plane is different at different temperatures, being very near a (110) plane at 100° C., and a (112) plane at 300° and 20°. It appears that the gliding is not connected with the closeness of packing of the planes.

Limitations of High-Voltage Insulation

DR. WHITEHEAD, of Johns Hopkins University, communicates an interesting paper to the *Journal of the Franklin Institute* of September on the limitations of high voltage. Fifty years ago, it was thought that electrical transmission distances in America would never go much beyond 150 miles and that the economical voltage would not rise much above 110 kilovolts. The grounds for this opinion seem to have been that the distances between available sources of power, whether hydraulic or steam, were never greater than about 300 miles. At the present time, there are not many transmission systems for distances greater than 150 miles, but there are several working at 220 kilovolts. A conspicuous example is the Boulder Dam—Los Angeles transmission line over a distance of 300 miles at 287 kilovolts.

Calculation has shown the economic advantage of power development and transmission to greater distance at a higher voltage. Dr. Whitehead discusses the limitations placed on a further increase of transmission voltage by the insulating properties of the materials which are at present available. Those most commonly used are the atmospheric air, ceramic materials such as glass and porcelain, petroleum oils and various composite fibrous materials such as impregnated paper. The important electrical properties of the materials used for the insulation of high-voltage circuits are conductivity and electric strength. The conductivity measures the ability of the material to withstand slow leakage, and the electric strength measures its ability to withstand breakdown or actual failure and short circuit. All materials, including liquids and gases, have some electrical conductivity, but they vary over a very wide range, the conductivity of copper being 10^{20} times greater than that of a good mineral oil. Those with high insulating properties may vary a million times between themselves, but they are all classified as available for high-voltage insulation.

All the materials used for insulating high voltage must have high electric strength. Usually the overhead high-voltage transmission line depends on the atmospheric air for its insulation. The conductivity of the air is so small initially that it can be neglected. As there are always a few ions present, they move backwards and forwards under the forces exerted by alternating high voltage, and when they move fast enough they have collisions with neutral ions, thus creating new ions and increasing the conductivity of the air between the lines. This causes the well-known corona or brush discharge surrounding the conductors. The discharge increases the conductivity and energy loss in the air and is thus a limitation to its insulating properties. Up to the present, it has been found possible—notwithstanding the great increases in voltage values—by separating the conductors sufficiently and increasing their diameter, to prevent coronas from forming. In the Boulder Dam line the main conductors are hollow and 1·4 inch in diameter; they work at 285 kv. To get a corona the voltage would have to be increased to 450 kv.

It appears that the saving effected in conducting material at higher transmission voltages is partly offset by the increased cost of the insulation. The higher the voltage the greater the cost of the insulation and the construction of the line, as the minimum total cost must always determine the most economical value of voltage. We have reached a stage in raising voltage values where the physical dimensions of the line are so great as to be practically prohibitive. To meet these limitations, special forms of construction of the conductor system and special auxiliaries to the insulation system have become necessary, and these impose further limitations to increasing the voltage.

For these reasons, engineers are studying the use of underground cables for high voltages. There are now several installations at 132 kv. and a few at 220 kv. Some of these systems using 'oil-filled' cables have given satisfaction for more than seven years, and credit is due to the engineers in the experimental laboratories where they were developed.

Building Research*

A SPECIAL feature of the report of the Building Research Board for the year 1936 is the retrospect prepared by the Director, Dr. R. E. Stradling, reviewing the progress made during the eleven years since the Station was established in its present laboratory at Garston, Herts. For four years previously the organization was taking shape, and the value of the experience then gained may be judged from the progress made since 1925. The work of the Station goes ahead continuously and, in knowledge of materials and methods and in experience, considerable progress has been made, but it is seldom possible in any one year to chronicle any definite advance. Over the longer period the work can be seen in better perspective, the import of it becomes more evident and lines of future development are more clearly indicated.

For example, the Library begun primarily for internal service with a stock of two thousand items, has increased fully tenfold in size and has become a focal point for world-wide information regarding all matters appertaining to building. Its functions are not merely to stock all this material, but also to include its study and documentation for the promotion of research and assistance in inquiries. The fact that this work of the Library, its resources, and the kind of service it can provide are insufficiently well known outside, justifies special mention of them in detail, for, as the Director notes, there is no reason why these services should not be equally available for the assistance of outside bodies as are those of the experimental and other facilities of the Station.

---

* Department of Scientific and Industrial Research. Report of the Building Research Board, with a Report of the Director of Building Research for the Year 1936. Pp. vi + 210 + 25 plates. (London: H.M. Stationery Office, 1937). 4*s*. net.

A branch of the work which has expanded rapidly during these years is that of dealing with technical inquiries. In the past year the number of inquiries received from architects for advice on the problem of sound transmission in buildings has been commented upon. On this subject investigation shows that the solution is primarily a matter of planning, as structural precautions can mitigate but not eliminate the discomfort of having noisy and quiet rooms adjacent. The report indicates that the most promising method of dealing with the transmission of noise in buildings is the provision of what is described as a 'floating floor'. The special investigations carried out in this branch also include those which are necessary to resolve difficulties or problems met with in practical operations, and the independent testing carried out for manufacturers of proprietary products. Reference is made to several of the most important or interesting of these in the report.

During the period a vast amount of work has been done on, and in connexion with, building materials —stone, brick, concrete, etc.—and the continuance of these activities is indicated. About those, their properties and limitations, much information has been obtained and made available for use. The investigations on bricks and brickmaking clays having been brought to a stage at which they can usefully be applied, attention is now being given to what is referred to as the efficiency of the brickwork structure as regards such matters as strength, permanency of bond, thermal insulation and exclusion of rain. In the cleaning of the exteriors of buildings the use of chemicals is condemned as destructive, and a process is recommended in which fine jets of water are employed for a period dependent on conditions, and this is followed by brushing. It is held that this gives satisfactory results without causing immediate or ulterior damage to the stone or even to carvings on it.

Among the major investigations made during the year were a series of tests to ascertain the resistance of I-beams of high tensile steel and of mild steel to failure by bend yielding of the flanges, by shear yielding of the web and by buckling of the web. Where necessary the surfaces were scraped and painted with a thin coating of plaster of Paris, the flaking of which indicated local yielding; this is clearly seen in the photographs taken during the tests. On behalf of the Ministry of Transport, tests were made during the year on six bridges; some particulars are given of these, but the data obtained have yet to be completely analysed. Three of the bridges were tested to destruction—a stone arch bridge of 21-ft. span built in 1793 collapsed under a load of 77·6 tons, a brick arch bridge of the same span and date failed at 123 tons, while one constructed in 1870 of cast iron beams and plates, with a span of 13 feet, broke under 74·6 tons, in each case the load being applied by hydraulic jacks at the centre of the span.

The record of work and results as set out here fully justify the Board in its statement that in this short period the Station has become a real factor in the building industry.

Eskimo Origins

THE essay on the origins of the most ancient civilization of the Eskimo, for which a prize was awarded by the Danish Government to Mr. Henry B. Collins, jun., in 1936, is now published under the title "Archæology of St. Lawrence Island, Alaska" (Smithsonian Misc. Collect., **96**, 1).

The essay takes as its starting point a descriptive account of the results achieved by the author and others in excavations on ancient sites in St. Lawrence Island, which established the succession *Old Bering-Punuk-modern Eskimo* in Western Eskimo culture. On the basis of this material it has been possible to make a detailed comparison not only of the elements of the two prehistoric and the modern cultures *inter se*, but also of this Western Eskimo culture, both as a whole and in each of its phases, with the other Eskimo groups, ancient and modern, including the Thule culture of Th. Matthiassen, the Caribou Eskimo of Kaj Birket Smith, and the Eastern Eskimo, as well as the neighbouring aboriginal peoples and cultures of America and north-eastern Asia.

In arriving at a series of general conclusions a number of problems come under consideration.

As regards the relation of the Western Eskimo and the Thule cultures, it has been demonstrated by Matthiassen that the Thule culture must have originated in the west along the Alaskan or Siberian coast, north of Bering Straits. This is now seen to be within the range of the Old Bering Sea and Punuk cultures; and on the basis of the St. Lawrence Island finds, it is shown that the Thule culture is more closely allied to Punuk of a late stage and the modern culture than to the Old Bering Sea culture. The Thule culture has also been shown to be close to the modern Point Barrow Eskimo. There is a close relationship between the Old Bering Sea culture and the prehistoric or Birnirk culture of old Point Barrow sites—the Birnirk culture, in fact, was, in part at least, contemporaneous with the old Bering Sea culture, while the modern Point Barrow is the closest to the Thule, possessing a number of important Thule elements, absent in the Birnirk culture.

This prominence of the Thule elements in modern northern Alaska is explained as due to a late return migration within the past few centuries of Thule Eskimo, after the original eastward spread of the Thule culture, which had developed out of the Birnirk, rather than the Old Bering Sea culture. This inference of a late migration westward is supported by the cultural, linguistic and physical uniformity of modern Eastern and Western Eskimo, while the physical characters of the modern Point Barrow Eskimo are quite distinct from the skeletal material from old Point Barrow sites.

The hypothesis that the north coast of Alaska has been subjected to a relatively late wave of migration from the east would serve to explain the view that the Eskimo had entered as a wedge at Bering Strait, breaking off earlier connexions between the

Palæo-asiatic tribes of Siberia and the Indian tribes of the north-west coast of America, for which the strongest evidence lies in their mythologies.

As to the place and cultural stage at which the Thule culture originated, indications, at present far from definite, point to a period late in the Birnirk cultural stage, which itself must be regarded as an outgrowth of the Old Bering Sea culture, but with an even closer relationship to Punuk. Sites intermediate between Birnirk and the oldest eastern Thule sites excavated by Matthiassen are much desired.

The weight of evidence is against the Aleutian Islands having served as a migration route from Asia to America. The known cultural remains of the Aleutians are of an essentially Eskimoid or American character, showing that the islands must have been peopled from the Alaskan mainland. It would have been no difficult undertaking for such expert navigators as the early Aleuts to push on to the Commander Islands and Kamchatka, while the reverse journey is improbable for Asiatics. The character of the American (Alaskan and North-West) affinities in Kamchadal and Koryak culture and mythology favour the southern route from America to Asia over the Aleutian chain.

Although on theoretical grounds we are forced to assume that man originally entered the American continent at Bering Strait, archæological work in this region has as yet revealed no trace of these earliest immigrants; nor has any trace of pre-Eskimo culture been found on St. Lawrence Island. It has, however, been shown that the Old Bering Sea culture of St. Lawrence Island is basic to existing phases of northern Eskimo culture from Siberia to Greenland. The bearing of the Alaskan investigations on the theory of a central origin of Eskimo culture is to show that the view put forward by Kaj Birket Smith of Caribou Eskimo culture as a form of proto-Eskimo is untenable, demanding as it does that this culture should have been static through a period of hundreds, or even thousands, of years, while everywhere else Eskimo culture was undergoing marked changes.

The existence of a number of elements in the Old Bering Sea culture, such as toggle-harpoons, sledges, kayak, etc., which are of widespread distribution in the Old World, but in the New World are found only among the Eskimo, points to an Old World origin for a culture which embodied the general features of Eskimo culture as we know it in its earliest western form; while certain indications suggest north-east Siberia, between the mouths of the Anadyr and Kolyma Rivers, as the area in which the Old Bering Sea culture in its specific form came into being.

Stimulation of Adventitious Root Formation by Chemicals

ON November 6, 1937, by invitation of the Director, a meeting to discuss the use of chemicals for stimulating the formation of roots on cuttings was held at the Royal Botanic Gardens, Kew. It is well known to botanists that, following the investigations on the Continent which led to the discovery, isolation and chemical identification of hormone-like substances controlling the growth of seedlings, these were found also to be capable of inducing the formation of adventitious roots. Since then, use has been made of β-indole-acetic acid and other synthetically produced substances in the hope that their application in aqueous solutions either directly in jars or by watering the compost would induce the formation of roots on cuttings. It would be of great value to horticulturists if cuttings of plants which do not 'strike' easily could be stimulated to do so in this way, or if the rooting of moderately easy subjects which are cultivated on a very large scale could be accelerated.

It is evident that an authoritative opinion concerning the practical value of these substances can be formed only as a result of co-operation between botanists, practical horticulturists and those who manufacture the chemicals. For this reason, those interested in the subject from these points of view were invited to the meeting at Kew. That interest in the subject is widespread may be judged from the ready response which was received to the invitation.

An unfortunate fact is that those plants which present most difficulty to experienced cultivators are in most instances precisely those which show least response to the application of chemicals that induce root formation. The degree of response exhibited by other plants appears to be more or less proportional to the ease with which they root without special treatment, the easiest subjects reacting with greater facility than the more difficult ones. So far as can be judged at present, the greatest hope for the practical utility of root-promoting substances will be in accelerating the rooting of woody cuttings of plants of 'medium' difficulty, as well as cuttings of herbaceous plants such as chrysanthemums which, although easy to propagate without special treatment, are cultivated on a very large scale. The production of a root system at the earliest possible moment is of great importance to nurserymen, especially with the latter type of material.

It will be appreciated that in the present state of knowledge the use of these substances is far from being a panacea for all propagating difficulties. Nearly everyone who spoke stressed the fact that the amount of experimental work which has hitherto been carried out on the practical application of these substances is too small to permit judgment on them to be passed. The fundamental physiological processes on which their activity depends are not at present understood at all. It has been known for many years that very dilute acetic acid possesses root-promoting properties, and its use has often been recommended to horticulturists. A point which needs elucidation is whether in fact the more complex root-promoting substances which have now come into prominence are superior to acetic acid. The small amount of experimental work to test this point which has so far been carried out rather indicates that they are, but the matter is by no means clear.

In view of the economic importance of the subject and the very varied experience necessary for assessing the value of various researches which are being or may be carried out on this subject in the future, a small committee of scientific workers and horticulturists is being set up, with headquarters at Kew, to discuss the practical value of the results obtained. It is hoped that the committee may serve as a medium for the exchange of ideas, and also as a body which may be consulted by those who are working at isolated centres and are not in a position to decide in what directions their researches might most usefully be carried out. If at any time it is felt that further open meetings could usefully be held, the committee will decide where and when these might take place.

University Events

CAMBRIDGE.—The title of Stokes lecturer in mathematics has been conferred on Dr. S. Goldstein.

The Vice-Chancellor gives notice that the Cavendish professorship of experimental physics is vacant by the death of Lord Rutherford. A meeting of the electors will be held on February 11. If a proposal which is at present before the University is approved, the stipend of the professor will be £1,400 a year or while the professor holds a fellowship of a College with dividend £1,200, in addition to a non-pensionable payment of £200 a year for administration. Candidates for the professorship are requested to communicate with the Vice-Chancellor, and to send him on or before February 1 ten copies of any statement or testimonial which they desire to submit to the electors. If testimonials and references are sent they should not, taken together, exceed four in number.

The Adam Smith Prize is awarded to S. R. Dennison of Trinity College.

OXFORD.—S. J. Wright, for some years assistant-director and recently acting-director of the Institute for Research in Agricultural Engineering, has been appointed director.

Dr. J. R. Raeburn has been appointed a research officer under the Committee for Rural Economy.

A. G. Ogston has been elected to a fellowship at Balliol College for work in the biological sciences.

Dr. A. G. Gibson, Nuffield reader in morbid anatomy, has been elected to a professorial fellowship at Merton College.

Viscount Cecil of Chelwood has been appointed Romanes Lecturer for 1938.

The numbers of those reading the various main subjects of study in the academic year 1936–37 have recently been compiled. The largest science 'schools' are chemistry (207), physiology (194) and mathematics (143). Then come the new school of geography (100), agriculture and forestry (76), physics (59), zoology (40), engineering, botany and geology. About nine per cent of those reading these subjects are women. These numbers are greater than the corresponding numbers of the last survey. They are still small, however, compared with those of many other subjects. History (931), 'Greats', philosophy, politics and economics, and modern languages have each more than twice as many students as chemistry. Then come, in descending order of numbers, law (405), English, theology, music and Oriental studies.

SHEFFIELD.—The following appointments have recently been made: R. W. John, to be research assistant to the Department of Pathology; Douglas Harrison, to be assistant lecturer in electrical engineering; Donald Havenhand, to be assistant lecturer in metallurgy.

Science News a Century Ago

An Ascent of the Peak of Demawund

At a meeting of the Royal Geographical Society held on January 8, 1838, extracts were read from three communications. One of these was an account of an ascent of the peak of Demawund in September 1837 by Taylor Thomson, the paper being presented by W. F. Ainsworth (1807–96), who had been surgeon and geologist to the Euphrates expedition of Colonel Chesney. The mountain, it was stated, was about 40 miles east-north-east of Teheran and previously there had been no account of its ascent by a European or any measurement of its height. Thomson left Teheran on September 4, and after obtaining guides at a village, ascended to the summit on September 9 and spent the night there in a cave which was heated to upwards of 76° F. by the sulphurous vapour which issued from the rocks. The geological formation of the mountain, from Gernah upwards for about 1,000 feet seemed, said Thomson, to be a bed of sandstone of the coal formation, with one seam of coal; above this limestone occurred with a thickness of about 1,200 feet, then came greenstone coloured with iron to within 100 ft. of the summit, which was a deposit of pure sulphur. "The geological results of this expedition," said Ainsworth, "possess great interest by establishing the existence of a pseudo-volcano in these central districts of Western Asia, and ally themselves with the observations which Baron Humboldt has made upon the evidences of volcanic action, which he has traced everywhere on the great continent of Asia. It is a remarkable fact that throughout those districts of Taurus, Amanus, Kúrdistán and the Persian Apennines, in which I have travelled, I have never yet met with rocks of the secondary series. The absence of every member between the chalk and the primary formations is one of the most remarkable features in the geology of Western Asia."

Fossil Discoveries in France

On January 13, 1838, the *Athenæum* again directed attention to the recent discoveries of fossils in a French mine, remarking that "Further inspection increases the importance of the discoveries of M. Lartet and others . . . and fresh arrivals from him at the Academy of Sciences in Paris, produce new wonders. They combine the remains of animals, which, in all probability, no longer exist in nature, with some which do not appear to differ from those actually in being: the mine is still far from being exhausted, and a more favourable opportunity for the observations of geologists never before presented itself. The bones of the rhinoceros most abound; after these come those of deer, with their horns, and if an estimation may be formed by their size, the remains of a small and elegant species of ass or horse must have been deposited. New fragments of *macrotherium gigans* have come to light, which show that its claws bore a strong analogy to those of the Oryceteropus. The bears must have been totally different from any yet discovered; and those bones which belong to an animal called Amphicyon, by M. Lartet, show a strong analogy between it and the dog".

Samuel Woodward, 1790–1838

On January 14, 1838, Samuel Woodward, the Norwich geologist and antiquary, died at the age of forty-seven years. Born in Norwich on October 2, 1790, he was the only son of a bombasine weaver. His father died in 1795, and at the age of seven years he was placed with a shawl weaver, but from the age of fourteen for ten years he worked with a manufacturer of bombasines and camelots. His taste for reading was stimulated by his employer, and he became a teacher in both evening and Sunday schools. In 1814 he obtained a clerk's place in the Norwich Union Fire Office, and in 1820 a similar post in Gurney's (now Barclay's) Bank at Norwich and this he retained for the remainder of his life. Devoting his leizure to the study of the history of his native county, he wrote on its churches, its antiquities and its geology. In 1830 he published "A Synoptical Table of British Organic Remains" in which for the first time all the known British fossils were enumerated, and in 1833 his work "An Outline of the Geology of Norfolk". One of his sons, Bernard Bolingbroke Woodward (1816–69), became librarian in ordinary to Queen Victoria at Windsor Castle, and another, Samuel Pickworth Woodward (1821–65), in 1845 became the first professor of geology and natural history at the Royal Agricultural College, Cirencester, and from 1848 until his death was an assistant in the department of geology and mineralogy of the British Museum.

Societies and Academies

Edinburgh

Royal Society of Edinburgh, December 6.

H. J. Bhabha: Production of electron showers by cosmic rays. Blackett and Occhialini showed in 1932 that cosmic rays produce showers. The quantum theory is capable of explaining these showers. Very high energy electrons lose practically their whole energy by emitting a few high energy quanta. Each high energy quantum is chiefly absorbed by the creation of a pair of positive and negative electrons. When, therefore, a very high energy electron passes through matter, it emits a few hard quanta, each of which in turn produces an electron pair, which again emit quanta and so on. Thus, if the initial energy be high enough, many hundred particles may be created, forming a shower.

R. S. Barclay and W. O. Kermack: The decline of the birth-rate: regularities revealed by an analysis of the rates observed in certain European countries. An analysis of the birth-rates in Sweden, Denmark and Finland has been made by a method analogous to that previously employed by Kermack, McKendrick and McKinley in connexion with the death-rates of Scotland, England and Wales, and Sweden. As in the latter case, regularities of a somewhat simple type are revealed. The results are applied in the calculation of specific fertility rates for England and Wales for the past six decades.

J. Small: Quantitative evolution (4, 5 and 6). (4) The effect (K) of an organismal factor depresses the apparent *Dp*-ages of Compositæ in direct proportion to time. This rectilinearity indicates that species in Compositæ have a limited life-time, and that genera are similar. (5) The K values give 'free' *Dp*-ages which do not depart significantly from a rectilinear series in time. (6) The *Dp*-age unit is 2 million years for angiosperms. Their normal species life-time is 12 million years, with generic life-times at 24 million years. Consequential data are given for residual doubling in numbers, also present rates for origins and extinctions. It is concluded that the presence or absence of eliminative natural selection is a matter for statistical inquiry.

T. M. Macrobert: Induction proofs of the relations between certain asymptotic expansions and corresponding generalized hypergeometric functions. The formulæ are established for simple cases by contour integration, and are then deduced for the general cases by induction. They are then employed to evaluate integrals involving Legendre functions and hypergeometric functions.

Paris

Academy of Sciences, November 22 (*C.R.*, 206, 941–1020).

Claude Chabauty: The units of a body of algebraical numbers which are submitted to algebraic conditions.

Paul Vincensini: A characteristic property of conformal transformations of the plane.

Fernand Aimond: Some properties of surfaces deduced from the conditions of equilibrium of convex surfaces.

Marcel Decuyper: Series of Laplace any four consecutive radii of which form a quadrilateral.

A. P. Dietzmann: Infinite groups.

Armand Rauch: Certain integral functions of the order $\rho < 1/2$.

Alexandre Favre: The study of the Toussaint-Carafoli hydrodynamic tunnel with the view of obtaining bidimensional movements. Flow with circulation.

Robert Silber: The influence of the blast from the propelling screw on the carrying power of an aeroplane, and the method to be followed for utilizing the results of tests of carrying power of a wing submitted to an air current from a screw.

Paul Muller: A new double image astronomical micrometer. A modification of the method used in the Rochon telescope. The instrument has been in use in the 16 cm. equatorial of the Strasbourg Observatory since January 1937, and has proved satisfactory.

Jean Mercier and Jean Dubois: Contribution to the study of solid friction. Preliminary studies on the variation of the coefficient of friction caused by changes in the pressure and the velocity.

P. L. Violle: Concerning Dewar flasks. The earliest description of a high vacuum and silvered surface in a glass flask for the purpose of reducing radiation appears to be that of J. Violle in 1882.

Henri Moreau: A preliminary study of precision mercury thermometers in fused quartz.

Leonid Gabrilovitch: Sorting waves by periodically variable resistance systems.

Wilfried Heller: The influence of the size of colloidal particles on their optical anisotropy.

Maurice Cotte: The orthogonal systems of electronic optics and their application to spectroscopy.

Pierre Barchewitz: The (CH) absorption bands of saturated and ethylene hydrocarbons between 6000 and 9500 A.

Maurice Lambrey: New observations on the disengagement of nitric oxide by various nitrated products at a low temperature. From a study of the gases evolved from crystallized tetranitropentaerythrite, it would appear that the true decomposition velocity is not measurable below a temperature of 50° C. This conclusion is confirmed by applying the same method to nitrocellulose powders stabilized with diphenylamine.

Edouard Rencker : Dilatometric researches on tempering and annealing of boric anhydride glass.

C. Zenghelis and El. Stathis : The formation of colloids by hydrogen. Salts of gold, silver, platinum and palladium are readily reduced by zinc in acid solution or by aluminium in alkaline solution ; but the reduced metals are not colloidal. By the addition of a little gum to such solutions the metals are readily produced in a stable colloidal condition.

André Borocco : The comparative study of the dissociation pressures of sodium and potassium hydrides and deuterides. Measurements made by a differential method show that the deuterides have higher dissociation pressures than the corresponding hydrides.

Martial Félix Taboury and Elie Gray : The corrosion of zinc in distilled water alone or in the presence of a gaseous atmosphere.

Siegfried Halberstadt : The exact conditions of the formation of the compound of tungstic acid and *o*-oxyquinoline. The precipitation is quantitative when the pH of the solution is 3·5 : in the presence of phosphoric acid, none of the latter is coprecipitated.

Charles Courtot and André Bernanose : Phenomena of chemico-luminescence, in the visible spectrum, of molecules containing the amide group.

Daniel Bodroux and René Thomassin : Syntheses of paracyclohexylbenzylic aldehyde and of paracyclohexylbenzoic acid.

Antoine Willemart : Homologues of para-anthracene : polymers of 9-methylanthracene and of 9-ethylanthracene.

Jean Kandel : The catalytic hydrogenation of β-ionone : dihydro-β-ionone, dihydro-β-ionol. Some derivatives of α- and β-ionol.

Paul Gaubert : Liquid crystals obtained by sublimation.

Pierre Bellair : The sandy formations of eastern lower Provence.

Georges Déjardin and Albert Arnulf : The ultra-violet absorption spectrum of atmospheric ozone. Except for the effect of temperature, there is no appreciable difference of structure between the spectrum of atmospheric ozone and the spectrum observed in the laboratory.

Théodore Solacolu and Démètre Constantinesco : The modifications undergone by seedlings after remaining a relatively short time in solutions of β-indolyl-acetic acid. β-indolyl-acetic acid is capable of stimulating the plant cell after a short time of contact (15 minutes). The effects last a long time, even if the plant continues to develop in ordinary water.

Mlle. Anne Raffy and Maurice Fontaine : Determinations of flavin in the course of development in cultures of *Eremothecium Ashbyii*.

André Goris : The atisine of *Aconitum heterophyllum* and the anthorine of *Aconitum anthora*. Anthorine is identical with atisine (Jowett), and it is suggested that the latter name be retained for the alkaloid.

Henri Berrier : Substances of the type of plant auxines in the course of the evolution of *Bombyx mori*.

Jean Roche and René Combette : The reversibility of the denaturation and coagulation of methæmoglobin.

Gustave Guittonneau and Mlle Marie Bejambes: Chromo-resistance and calcium phosphate coating of micro-organisms heated in milk.

Raymond Hovasse : The Zooxanthellæ are dinoflagellates.

Constantin Levaditi, André Girard, Aron Vaismann, André Ray and Guy Richard : 4-Nitro-4-aminodiphenylsulphoxide and its action in the experimental toxi-infection of mice.

Copenhagen

Royal Danish Academy of Sciences and Letters

October 22.

Otto Neugebauer : Babylonian theory of eclipses.

November 5.

Knud Jessen : Contributions to the late glacial flora of Ireland.

November 19.

Niels Bohr : Mechanism of nuclear reactions. A discussion of the applications of thermodynamical analogies for the analysis of nuclear reactions.

December 3.

Harald Bohr and Donald A. Flanders : Algebraic equations with almost periodic coefficients.

December 3.

G. Hevesy and Ladislav Hahn : Origin of egg phosphorus.

December 3.

G. Hevesy and Hilde Levi : The artificial radioactivity of hafnium and some other elements.

Moscow

Academy of Sciences (*C.R.*, 16, No. 8, 1937).

V. A. Florin : Determination of instantaneous stresses in skeletons of soils.

G. S. Landsberg and S. A. Ukholin : Frequency of oscillations of the hydroxyl group in methyl alcohol and its dependence on the density.

S. A. Ukholin : Dependence of the spectrum of an aqueous compound on the density and the pressure.

V. L. Levšin and S. N. Rževkin : Mechanism of luminescence in liquids under ultra-sonic treatment.

A. T. Akimov : Specific electrical resistance of frozen soils.

L. Gindin and F. Šemiakin : Linear corrosion of metals. Selective corrosion of iron according to the system water-sulphuric acid-propyl alcohol, at the boundary of three phases.

L. Gindin, I. I. Torsujev and V. A. Kazakova : Relation to metals of sulphur solutions and of a series of organic sulphur compounds in saturated hydrocarbons. The relation to iron of ethyl- and butyl-mercaptan solutions in cyclohexane.

M. I. Kniaginičev and T. M. Gorelkina : New solvents of gluten proteins.

L. A. Dremliug : A frost-resistant triple potato hybrid, *Solanum acaule* × *S. tuberosum* (Furstenkrone) × *S. tuberosum* (*Centifolia*).

M. V. Favorskij : New fixatives for chromosome morphology.

G. V. Gershuni, A. M. Andreev and A. A. Arapova : Concerning the cochlear potentials in man.

V. S. Shardakov : Salt resistance of the cotton plant. Localization of salts in the leaf tissues.

Forthcoming Events

[Meeting marked with an asterisk is open to the public.]

Monday, January 10

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Eric Shipton: "The Shaksgam Expedition of 1937".

Tuesday, January 11

INSTITUTION OF CIVIL ENGINEERS, at 6.—Sir George Lee: "Recent Engineering Developments in the General Post Office".

Wednesday, January 12

SOCIETY OF GLASS TECHNOLOGY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 3–9.—Series of public lectures on "Glass in Modern Life".*

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

JUNIOR MAINTENANCE ENGINEERS (Grade V) at the B.B.C.—The Engineering Establishment Officer, British Broadcasting Corporation, Broadcasting House, London, W.1 (January 15).

TECHNICAL OFFICER at the Air Defence Experimental Station, Biggin Hill, Kent—The Superintendent (January 15).

JUNIOR LECTURER IN SOCIAL STUDIES in the University of the Witwatersrand—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2 (January 18).

LECTURER IN BIOLOGY in the Cardiff Technical College—The Director of Education, City Hall, Cardiff (January 19).

SCIENTIFIC ASSISTANT (chiefly biology) to the Metropolitan Water Board—The Clerk of the Board, 173 Rosebery Avenue, London, E.C.1 (January 21).

DEMONSTRATOR IN ENTOMOLOGY in the Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, 3 (January 31).

CAVENDISH PROFESSOR OF PHYSICS in the University of Cambridge—The Vice-Chancellor (February 1).

GEORGE HOLT PROFESSOR OF PATHOLOGY in the University of Liverpool—The Registrar (February 12).

RESEARCH CHEMIST in the British Colliery Owners' Research Laboratory, Royal School of Mines, South Kensington, S.W.7.

ASSISTANT (grade III) in the Aerodynamics Department of the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (Quote Ref. No. 641B).

The British Association and Imperial Unity

THERE are plans for ensuing peace which may seem on a hasty or superficial view to have little or nothing in common. A closer analysis, however, shows that, in many instances, points of contact are exhibited such that men of good will, seeking to save our civilization from the dangers that beset it, may find in the structure of very divergent plans some greatest common measure which will make possible effective united action.

The policy of the British nation, as it is expressed by the National Government, is one of firm support of those principles of collective security set forth in the Covenant of the League of Nations. To that end is the national scheme of rearmament directed ; to that policy—a policy which recognizes that the older method of denying to one's opponent the justice which one claims for one's self is neither right in morals nor effective in action—we are committed over and over again, if words have any binding significance. It is the plain duty of every citizen who supports that policy to use to the utmost such powers as he possesses to bring the ideals of the Covenant of the League of Nations into the realm of fact. The need is urgent, and opportunities, once lost, are not likely to recur.

What part can the man of science play in this world-drama ? His responsibilities are great and, while he cannot, in common fairness, be asked to shoulder all the blame for the misuse of the great gifts which the genius of his predecessors and contemporaries has showered upon mankind, it is in some measure his responsibility in that he has placed dangerous weapons in the hands of those whose minds are not mature enough to use them wisely and well.

Mayhap the man of science himself, considered as a social animal, is still in that stage. This is possible, but unlikely, for the scientific worker to-day is showing himself increasingly alive to the importance of the impact of the advance of knowledge on society, whether the society be that of the nation or the world at large, and the toast "Here's to science—may it never be of any use to anyone at any time" is drunk with less and less enthusiasm as the century grows older.

Nowhere is that increasing awareness more clearly shown than in the programmes of the British Association. Some years ago, the Council considered carefully how the Association, within the framework of its constitution, could most profitably assist towards a better adjustment between the advancement of science and social progress. Effect has been given to these considerations by specially distinguishing papers, addresses and discourses which have a direct bearing on the relations between science and the interests of the community, and by arranging that, at each annual meeting, a proportion of the work of the meeting shall be devoted to the elucidation of such problems.

The efforts made in this direction have been widely recognized and appreciated, but are they a sufficient contribution to the general problem ? Such work, though it makes contact with imperial and international matters in so far as it concerns itself with social questions of wide interest, yet barely touches the fringe of those problems which, unwisely and irrationally attacked, may lead the world down the ringing grooves of change to a goal which shall see the shattering of all those ideals for which a sane civilization stands.

The problem is as much emotional as rational. Even if the Association directly concerns itself—as we earnestly hope it will—with finding scientific solutions for some of the social and economic problems which deface and weaken the structure of our international relations, such rational solutions will be but one step towards that freedom from national animosities and clashing interests which is the greatest guarantee of international peace.

For the British nation, the first guarantee of peace, internal or external, is a united Empire, united, not by the bonds of self-interest, enlightened or not, but by a sympathetic understanding of each other's difficulties and problems; and that is equally true of the relations between nation and nation. It is the creation of a friendly spirit of good will that matters most, and it is a favourable omen for the future that the Association, in the most recent of its activities, is directing its energies towards a task which will assuredly increase the spirit of good will and understanding between the constituents of our Empire. The sending of a delegation nearly a hundred strong to the silver jubilee celebrations of the Indian Science Congress Association is an event unprecedented in the history of the British Association. Over-seas meetings are an old-established feature of the Association's work, but the sending abroad of an independent delegation during the year of an ordinary meeting at home is quite another story. Lord Rutherford, with his accustomed wisdom, quickly perceived the importance of this step, and his considered opinion, expressed with that lucidity and emphasis which were part of his being, was that the Association could undertake no more important work than that of sending delegations to outlying parts of the Commonwealth, and that the success of the British Association in days to come would in no small measure depend on the development of its activities in these important directions.

Lord Rutherford, in more regions of thought than that of physical science, had an uncanny gift for seeing the answer to the sum without going through the dull mechanick process of working out the algebra, and in this matter, as in many others, it is more than likely that he spoke with a wise prevision. The British West Indies, Kenya Colony, Malaya . . . each has its problems, social, educational and scientific, and a visit by a delegation from the Association to one of these Dependencies, or to those greater Dominions which already know something at first hand of the Association's activities, would be welcomed as giving to the region visited some direct knowledge of the most recent advances in science, affording an opportunity for the discussion of special problems, and, more than all, of cultivating that spirit of mutual aid which is at the root of all healthy social life. Is it too much to hope that, within the next few years, we shall see a delegation formed which shall carry a message of good will to the British West Indies?

The work of such delegations by no means exhausts the possibilities. The Association carries on much of its work quietly during the intervals of its meetings by means of research committees, appointed at the annual meeting. The researches of these committees have done much to systematize and clarify our knowledge, and in many instances have resulted in important additions thereto. It is sufficient here to instance the work of the great committee on Electrical Standards and of the committees on Seismological Investigations and on the Calculation of Mathematical Tables. There are many Imperial economic and other problems which might profitably be attacked by research committees acting under the ægis of the Association. It would be very desirable, also, to extend hospitality more frequently to students from the outlying posts of the Empire who desire to take part in the ordinary meetings of the Association. More than this, there are possibilities, so far imperfectly explored, of sending delegations to the meetings of sister Associations in other countries, thereby doing something to promote that atmosphere of mutual understanding which is such a powerful dissipator of jarrings and jealousies.

Each of these activities, considered as a contribution to the causes of Imperial unity and of international peace, may be in itself a little thing; but a little thing well done is a very great thing, and, indeed, the sum total of these matters is far from being small. The prosecution of these tasks will involve the Association in grave financial responsibilities, responsibilities which for these great causes are well worth incurring, and the Association could raise no more enduring monument to the memory of the great physicist who has so recently left us, than by the institution of a series of delegations to be known for all time as the Rutherford delegations, and to be charged with the duty of fostering the unity of the Empire by carrying the lamp of science and learning to her uttermost dependencies.

A Philosophy of Science

Through Science to Philosophy
By Prof. Herbert Dingle. Pp. vii + 364. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 15*s*. net.

PROF. H. DINGLE here expounds a philosophy of science on a purely phenomenalist basis. It is the kind of philosophy that no one believes in except at the moment of philosophizing, and for that reason is difficult to work out systematically without lapsing into more ordinary ways of thinking. Nevertheless, the effort is worth while as providing a test case. We can discover the primary assumptions necessarily presupposed in scientific thought only by the method of working out extreme theories which try to dispense with or contradict common assumptions. In the reviewer's opinion, some of Prof. Dingle's assumptions are wrong and his theory will not work, but he has made a valuable contribution to thought in that he has developed this type of theory more clearly and consistently than others who have put forward phenomenalist or positivist views. In particular, it is far better than the efforts of those who call themselves Logical Positivists, who have so entangled themselves in an impossible logical or linguistic theory that they never get so far as to discuss anything of interest.

The author's main assumptions may be set out as three negative and five positive statements. (1) There is no 'external world' about the nature of which science gathers information. (2) The common-sense dualism of matter (as something existing on its own and moving and extended in space and time) and mind (as something which is aware of matter) is to be rejected. (3) The common-sense theory of 'physical objects', namely, that there are things, like tables and chairs, to which certain groups of perceptible qualities necessarily belong, is to be rejected. The concept of 'physical objects' Prof. Dingle considers to be not merely crude and needing refinement, but also definitely incompatible with scientific method, and therefore to be totally rejected. The positive assumptions are as follows: (1) The starting-point for science is simply my awareness of the data of my sense experience, interpreted in a solipsist sense, as though I were the only observer. (2) The only dualism admitted is the contrast between fact (or experience) and reason (or the concepts used in co-ordinating facts). (3) Experience consists of present and past data; ultimately of 'atoms' of experience which can be grouped at will into 'molecules' of experience. All reasoning processes necessarily deal with past experience or memories. (4) My own private experience is expanded by including 'pseudo-experience' due to communications from other people. That is to say, spoken or written words are not taken simply as they are, but as representing what might have been my own experience, and so take their place in memory as representatives. (5) Science consists in correlations between atoms of experience made by means of concepts, which are creatures of reason created for this purpose and to be altered as required, within the limits of the laws of logic.

On these lines, Prof. Dingle proceeds to expound modern physical theory. In fact, he is able to deal very easily with a number of outstanding problems and paradoxes; such as causality and the uncertainty principle, the treatment of unobservables, the puzzles of time measurements, and the question whether the universe is 'running down'. Incidentally he criticizes views expressed by Sir Arthur Eddington, Prof. E. A. Milne and others. All these subjects are dealt with in a very interesting way and, granted the assumptions, the conclusions are reasonable. What it comes to is that ordinary physical theory can be translated into Prof. Dingle's language without apparent loss and, in some respects, with considerable gain in simplicity and clarity. The difficulties of his theory do not lie here, but further back in his repudiation of physical objects and what he says about fact and reason. The stumbling-block is not physical theory but the process of observation.

It is the function of reason, Prof. Dingle says, to find correlations among facts. The facts are simply my memories. But memory may deceive me, and give me apparent facts which refuse to be correlated, as when I forget things or remember them wrongly. Such facts, he explains (pp. 62, 163–164, 188 *seq.*) are rejected as physical facts and become merely psychological facts. That is to say, if I remember something which does not fit in with my theories, I take it as being no part of the world of physics but as a peculiar mental process, the causes of which the science of psychology might be able to explain if it were sufficiently advanced. This seems to make things too easy. It leaves us wondering why investigators take all the trouble they do to investigate a non-existent external world and why physical theories are so complicated as they are.

The author's views on the subject of observation are perhaps not unfairly represented by his statement (p. 292): "When we say we see a star our experience is simply that of a bright point." Notice the word 'simply'. What about the telescope which had to be designed, built, adjusted, maintained and finally directed towards some definite part of the sky ? If we did not bother to do any of these things ourselves, other people did and in their manipulations they were making use of the common-sense theory of physical objects and not of the author's theory. Even if we merely walk out of doors and look at the sky, our actions imply the existence of physical objects, our own bodies among them. The weakness of the phenomenalist theory comes out in the very inadequate account of biology in Chapter vi. The biologist has always clung firmly to a belief in physical objects. The weakness is also seen in the seventh chapter, which deals with psychology. If it is only the psychology of my own mind, there is no difficulty. But the author says that the actions of other people are "psychological movements". How do these differ from physical movements ? If it is because they are incompatible with physical laws, then physical laws are false or the observations mistaken. If they are compatible, what is the distinction ? The distinction is clearly one which Prof. Dingle is debarred from pointing out, namely, that they proceed from a peculiar type of physical object, the type to which I myself and other people belong. It is probably quite true that the formulation of physical theory does not require physical objects, but it does not follow that the concept must be abandoned, much less that it is incompatible with scientific method.

In conclusion, this is a stimulating book, always clear and often witty. It should be a useful corrective for experimental scientists lapsing into dogmatism, but may be dangerous reading for mathematicians.

A. D. R.

Forests and Forestry in West Africa

The Forests of West Africa and the Sahara: a Study of Modern Conditions. By Prof. E. P. Stebbing. Pp. viii + 245 + 49 plates. (London and Edinburgh: W. and R. Chambers, Ltd., 1937.) 15*s*. net.

THE author early raises two debatable issues: he considers that (1) the general use of the word 'savannah' in Africa is wrong; and (2) the use of this wrong term has misled both forester and layman into thinking that savannahs are useless and cannot be improved upon. The reviewer disputes both these points, on the grounds that (1) the savannahs of Africa to-day conform to the ecological type recognized as such, irrespective of their origin; and (2) Nigeria possesses some 8,000 square miles of savannah reserves, most of which have been under ameliorative treatment for many years, which refutes the second contention. Elsewhere in West Africa it may hold good, but the most recent literature and information (Marshall, "Gold Coast"; also Moor, Proc. Brit. Emp. for Conf., 1935) on the subject indicate a definite change in opinion.

The main points emphasized, however, in the early chapters (i–v) are the menace of soil impoverishment in West Africa, and that the present position is one of considerable danger. Here the author is certainly right. The cause, as in many other parts of the world, is man's misuse of the land, as a result of which considerable areas have become depopulated. Sand displacement would be a better term to use than sand accumulation, as apart from local drift-hollows and special localities (for example, Ténéré dunes) the movement is one of erosion; the drift soils seen to-day were laid down in a recent period of depression.

Incidentally, M. Aubréville, Inspecteur Principal des Eaux et Forêts, states (Aubréville, "Report on Colonie du Niger, 1935") that the Saharan dunes shown in the photograph facing p. 16 are ancient *fixed* dunes temporarily exposed by the removal of the millet crop; nevertheless, the exposure materially aids erosion. Prof. Stebbing rightly argues that a proper programme of reservation will do much to improve matters, but in connexion with this, on pages 39, 43–44, suggests that the selection of forest reserves should be done by the political and not by the forest officers; later on (p. 45) this is contradicted, and it certainly does appear uneconomic to allow a political officer to carry out scientific and technical duties when officers specially trained for the purpose are available. It is the generally accepted practice that, while the support of the political officer must always be enlisted, and while he *settles* the reserves, their actual selection rests with the forester; and, as by this means one West African country has added 5,000 square miles of reserve to its forest estate within the last five years, it would seem wrong to depart from it without cogent reasons.

The author gives some excellent advice in regard to reserve selection, but on p. 46 makes a statement that cannot go unchallenged: "So far the idea that the commercial forest is the only thing to look for and reserve has held sway, to the exclusion, or almost exclusion, of the equally important agricultural issues. . . ." This is not so in any of the English colonies; and reference to almost any report in West African forests from Moloney's time ("Sketch of the Forestry of West Africa", 1887) to the present will reveal that the value of protection forests and the aid they give to agriculture has ever been strongly emphasized; indeed, this formed a marked feature of the policy laid down by Sir Frederick (now Lord) Lugard ("Political Memoranda", 1918).

The suggested establishment of two great reserved zones right across the country is important; it is assumed that only forest (that is, savannah or 'fringing forest') within these zones will be reserved. While these belts of reservation will be of undoubted value, it is not made clear that they in themselves are not sufficient to form a 'climatic barrier', unless supported by intervening and well-distributed reserves of considerable magnitude; thus while concentrating to some extent on these 'tension belts', the interacting factors that justify reservation must be reviewed and used as the real guide to reservation throughout the country as a whole. But why omit the 'rain forests'? Apart from their commercial value (£500,000 annually) and apart from their strategic value, generally lost sight of, their situation gives them immense climatic significance.

The rotational treatment of farmland suggested in Chapter vi on a *bush-fallow* system improved by tree planting can only do good, and will particularly benefit those regions where so-called 'land-hunger' (that is, soil degradation) has reached an acute stage.

The organization in the Ivory Coast service (Chapter vii) is of interest. The comparison, however, would, for obvious reasons, have better been made with the Gold Coast rather than with Nigeria; the Nigerian organization (p. 63) is not correctly described, and consequently except from an academic point of view many of the observations on pages 64–68 lose much of their value; the same applies to certain remarks in the summary.

From a forester's point of view, Chapters viii–xii are the most useful in the book. They deal in considerable detail with different sylvicultural operations in parts of French and British West Africa. The field nurseries of the Ivory Coast under natural shade appear excellent, and it is also clearly shown that nursery methods depend not only on their locality but also on the specific purpose of the nursery. The fact that it is often easier to have too much shade in the dry zone than in the wet, as observed in the Ivory Coast, is well illustrated in the Nigerian photographs on p. 88. Stump-planting introduced into Nigeria in 1923 met with instant success, and apparently spread to the French colonies about ten years later; in 1935 Aubréville refers to it as a novel and savage, though successful, method. The different technique in Sierra Leone attracts attention. The records of 'rain forest' improvement work, too, are of considerable value and make interesting reading, collated as they are from several sources.

Some minor notes or corrections should be made in regard to the above chapters, namely: Tabe Nursery photograph (p. 89) "*Acacia*" should read "*Cassia*". Research in Togoland into the Iroko gall (*Phytolima lata*) occurred so early as 1912. Olokemeji Reserve is 25·19 square miles, not 2,519 acres. The sandalwood trees felled at the author's request at Olokemeji were scented, etc.

Details of the Ivory Coast forest concessions have been known officially in England and the Coast for some years, but the actual concessionaires' technique has not been recorded in English, nor previously has any direct comparison been made between French and English methods. The striking difference is the single tax paid by the English concessionaire and the numerous petty exactions levied on his French opposite number; the ultimate amounts paid are approximately the same. Rents are not charged on concession in English colonies, as they would fall unduly hard on the African concessionaire.

The concessionaires' methods differ somewhat, mainly because in the Ivory Coast certain factors necessitate a closer utilization and so more detailed 'cruising' methods. Such factors include a lower rate of wages, lower minimum girth-limits and a less particular market. Is it not a misprint to say that the English concessionaires only look three months ahead? The short account of Ijora mill, as the author says, proves an exception to the common belief that Government cannot manage a business concern, but the conversion percentage is startlingly high.

Coming from such a facile and distinguished pen as the author's, the publication is a little disappointing, and there are some noticeable omissions from a book which gives a 'wide grasp' of the forests of West Africa and which is a study of modern conditions. These omissions are the more marked as certain other operations are treated with such detail. For example: Why barely mention the Nigerian enumeration surveys? They were in full force in 1934. Ameliorative treatment of savannahs, initiated in Nigeria on an extensive scale almost twenty years ago and with markedly good results, is not mentioned ; indeed, by implication, its existence seems to be almost denied. Tsetse, for years a serious difficulty in forestry, is avoided.

Exploitation on the Gold Coast, one of the largest exporting countries in West Africa, with its own peculiar problems, is not referred to. No reference is made to progress in reservation : there are other omissions. The early wide view taken on desiccation, followed by the detailed treatment given to certain work, together with the omissions of at least equally important work, make the whole appear somewhat disconnected and almost misleading to anyone unacquainted with West Africa, and gives the impression that the country still deserves its former description of "West Africa the Elusive". It is a pity, too, that no mention is made of earlier work done by such men as Punch, Foster, Chevalier, Thompson, Unwin, Reder and others. On the other hand, attention has rightly been directed to the dangers arising from soil misuse and impoverishment, and many of the sylvicultural and utilization details collected together for the first time will prove very informative to West Africans and to those interested in that sub-continent. A good map would have enhanced the value of the work ; the photographs throughout are numerous and excellent.

J. R. A.

Developmental Abnormalities of the Eye

Developmental Abnormalities of the Eye
By Dr. Ida Mann. (Published for the *British Journal of Ophthalmology*.) Pp. xi + 444. (Cambridge : At the University Press, 1937.) 50*s*. net.

THE dependence of the empirical sciences on the pure sciences, and the essential value of research in the latter, even although at the time it seems merely academic and of little practical utility, if the former are to evolve on rational lines, are nowhere better exemplified than in the advances which have taken place in our knowledge of congenital defects and aberrations in the visual organs. Two factors have lately combined to revolutionize our conceptions of ocular malformations : a widespread interest in what may be called the science of experimental embryology, whereby defects are produced by chemical or physical traumata on the developing organism and, in some cases, are systematically perpetuated by in-breeding, and the immense improvements in the methods of clinical study rendered available by innovations in the technique of clinical observation, such as the slit-lamp, whereby minute changes which hitherto had either escaped attention or had been looked upon as incidental and of no importance, can be intimately studied and adequately assessed. As a result, quite a number of new developmental aberrations have been discovered in the last two decades, the common occurrence of others which before had been considered rare has been established, and in many more our knowledge has been widened and co-ordinated, so that what had hitherto been vague conceptions stimulating the elaboration of (in some cases) a dozen or more explanatory hypotheses by the ingenious, has been rationalized and set upon scientific foundations.

In this story of progress Miss Ida Mann has played a part which has been by no means inconspicuous, and alone in the English-speaking world, both by her original work and by her literary presentation of the problems raised by herself and others, can challenge comparison with such Continental names as v. Szily of Münster or Seefelder of Innsbruck. Some six years ago she published a monograph on the development of the human eye, which to-day is probably the most exhaustive and authoritative treatise on the subject in any language. There now has appeared as its logical successor an elaborate monograph on the developmental abnormalities of the eye, wherein the detailed information gathered in the first monograph is applied with the same authoritative knowledge and wide experience to the elucidation of the more practical problems of clinical medicine.

To many the study of congenital and developmental abnormalities may seem tedious and sterile : tedious because too often they are presented as a chain of shortly described, isolated morphological pictures ; sterile because, with few exceptions, they do not yield to treatment or amelioration. It is most refreshing to read this book and realize that this science need not be a mere catalogue of cases, to find that when these conditions are arranged against their appropriate background of comparative anatomy and embryology, and when they are considered not as separate entities but are marshalled consecutively, one leading up to and merging ætiologically into the other, their study becomes a series of fascinating stories.

The book is in every way a good one ; irreplaceable in so far as it is unique; comprehensive and reasonably exhaustive without becoming discursive; authoritative in that the work and theories of others receive criticism always penetrating and shrewd and very knowledgeable; and well-written in a clear and easy style. To some extent it is uneven in detail, for the author has enjoyed the writing of it and has not hesitated to enlarge preferentially on those portions of the subject to which she herself has contributed original work; but this is a good thing, for her interest and enthusiasm lighten the narrative and give it an intimate and personal flavour.

The monograph, like its predecessor, is sponsored by the *British Journal of Ophthalmology*, and those responsible are to be congratulated on their vision in producing a work of undoubted scientific importance which appeals to a small public; and Sir John Parsons has contributed a kindly foreword. There is a bibliography which is full but by no means exhaustive; and the illustrations are profuse and excellent; a very large proportion are original, and Miss Mann is an artist of merit. The printing and production show the usual finish and luxury of the Cambridge University Press.

S. D.-E.

Social Values of Science

What Science really Means:
an Explanation of the History and Empirical Method of General Science. By Julius W. Friend and James Feibleman. Pp. 222. (London: George Allen and Unwin, Ltd., 1937.) 7*s*. 6*d*. net.

THE average science graduate of to-day seldom receives a training in scientific methods, and, on the other hand, the few art students who are taught scientific method rarely have a scientific background for their studies. Accordingly, the failure of many scientific workers to appreciate or understand the principles of the scientific method is paralleled by a corresponding lack of knowledge of the potentialities and limitations of that method on the part of the educated community in general. The situation is the more serious as not only are scientific workers considering the social and economic consequences of their work more closely, but also the community in general takes a keener interest in the application of science to social as well as to industrial problems, and is apt to blame science for consequences for which it cannot reasonably be held responsible. This book should fill a gap in the training of the scientific worker and also give the general reader an insight into the methods of science, and some appreciation of their potentialities and limitations, which should to some extent prevent hasty and unfair judgments upon them.

In the opening chapters, the authors' review of the original development of empiricism and of the relations between experimental work and speculative reason leads to an explanation of some current misconceptions of empiricism, and will probably surprise some scientific workers by its indication of how far back experiment goes. The most suggestive and stimulating chapters of the book are, however, those in which the authors discuss the logic of science, causality and probability and the future of empiricism. These chapters not only administer a salutary corrective to the tendency to over-emphasize induction or deduction, and to discriminate between pure and applied science, but also stimulate sound thinking about the mechanism of discovery and the conditions of scientific progress. Especially welcome is the discussion in the final chapter of the reasons for the backwardness of the social sciences, and of the relation between science and society. The present position of social science is, in fact, largely attributed to failure to understand scientific method and consequent neglect of deduction. So far from pleading for the accumulation of further data, the authors urge that failure to synthesize the mass of uncorrelated data already accumulated is a definite obstacle to progress.

The condition of social science is, however, discussed from another point of view. It affects both the question whether science will be allowed to develop unimpeded, and also whether society itself will continue to develop. Unless social science guides technical developments their application may cancel each other, and without social science we can have no sufficient or authoritative judgment of good or bad. The final question is whether society will understand science in time for science to develop a science of society by which both science and society can be preserved. The authors are firmly convinced that social science is possible, but even here they stress the importance of the theoretical aspect and the need for the great specialization within individual sciences to be balanced by a general synthesis embracing all sciences and greater rationality.

The book can be heartily commended to those who have no time for a more detailed study, such as Bavink's "The Anatomy of Modern Science", but who wish to understand the nature of scientific method and obtain some background of scientific philosophy.

R. Brightman.

(1) Principles of Mechanics of Frozen Grounds

By N. A. Tsitovitch and M. J. Soumgin. Pp. 432. (Moscow and Leningrad: Academy of Sciences of the U.S.S.R. Press, 1937.) 13 roubles. (In Russian.)

(2) Vechnaa merzlota pochvy v predelach S.S.S.R.

By M. Sumgin. (Akademia Nauk: Souza Sovetskich Sozialisticheskich Respublik.) 2-e dopolnennoe izdanie. Pp. 379. (Moscow and Leningrad: Izdatel'stvo Akademii Nauk S.S.S.R., 1937.) 12 roubles.

(1) IN the first of these two books the authors have collected an enormous mass of experimental data almost entirely from Russian sources on the properties of frozen soils. The scope of the work is perhaps rather over-optimistically enterprising, but it may surprise those who are unable to keep up with recent Russian soil work that so vast a range of experiments should have been attempted.

Frozen soil is first discussed as a four-phase system, and the effects of freezing in producing heaving under various conditions are studied. This is followed by a very detailed account of work on many of the physical properties of frozen soils. Mechanical properties such as resistance to loading and shear occupy a considerable section of the book. It is a pity that some account of the work of Pigulevski on the shearing of soils is not included, and Pokrowski's experiments on loading receive only slight mention. Methods are described for measuring elasticity moduli, Poisson's ratios, and viscosities, though here, as elsewhere, one regrets that so little attention has been paid to any recent work outside the U.S.S.R. The effects of thawing are also discussed. The second part of the book deals with such practical applications as the effects of frozen soil on the stability of bridges and buildings. In areas where the soil is almost always frozen, the risk of rare thaws must be considered.

(2) The second book is a new edition of Soumgin's treatise on the distribution of permanently frozen soils in the territory of the Soviet Union. The first edition, published in 1926, has required considerable alteration to include the work described in (1). The book is intended for Russian readers, and although the maps are interesting its appeal will be much less general than that of (1). Both books would be the better for a wider bibliography, both Russian and foreign. G. W. S. B.

A Textbook of General Biology

By Prof. E. Grace White. Second revised edition. Pp. 667. (London: Henry Kimpton, 1937.) 15*s*. net.

THOUGH written by an American professor of biology for American students, this book, which takes a rather different point of view in elementary biology teaching, is worthy of bringing to the notice of teachers of biology in other countries. As a book of reference the teacher should find it very useful, though as a book for students it would be rather disconcerting, since the subject-matter is so different from that used for most classes, at any rate in Great Britain. For example, the first type animal in the book is the grasshopper.

Nevertheless, teachers should derive considerable inspiration from this well thought out and well-written work. It is divided into three parts. Part 1 deals with a typical plant and typical green plant, in all their aspects—physiology, morphology, etc. Part 2 gives the most recent conceptions of biochemistry, biophysics, cytology, and genetics. This is followed by very well-written and very important chapters on the history of biological thought, culminating in a review of present-day conceptions.

Part 3 is more stereotyped in its review of the organization of the plant and animal kingdoms. It is from Part 2 that British teachers of biology will glean most ideas for improving their presentation of the subject to students of all grades up to the Higher School Certificate standard.

The Spotted Lion

By Kenneth Gandar Dower. Pp. x + 331 + 24 plates. (London and Toronto: William Heinemann, Ltd., 1937.) 8*s*. 6*d*. net.

THIS is a book which will infallibly commend itself to the far from numerous class who, having experienced, love the African wild. Others will enjoy the reading, but the book is primarily for those who believe that "Kenya was worth more to the world when she produced wonders and imaginings than sisal and coffee", for those like the author who "hate the whole spirit of successful Bognorization which is disenchanting the land". Mr. Gandar Dower believes that the best he can hope for from his readers is the half-conscious thought, "Why, this is good", and from those who have known the old safari days he will doubtless obtain his desired verdict. For them the book, charmingly written, will come as a relief and a joy after the stereotyped routine of the usual expedition of to-day.

That no spotted lion was obtained, that such a variation of the normal animal may not even exist as a definite race, simply does not matter. The beast serves admirably as a peg on which to hang accounts of adventures very engagingly told. It should be added that the illustrations are excellent; one of a hippopotamus swimming and another of wild dogs over a kill strike the reviewer as especially good, but it is invidious to choose. Mr. R. I. Pocock, formerly of the Zoological Society's Gardens, contributes a "Note", leading, as he says, to "no precise conclusion". J. P.

Wanderings of a Bird-Lover in Africa

By Madeline Alston. Pp. 256 + 9 plates. (London: H.F. and G. Witherby, Ltd., 1937.) 8*s*. 6*d*. net.

THIS book, written with an obvious enthusiasm, will be appreciated more by those who know South Africa and its fauna than by naturalists living in the northern hemisphere. The birds are often described by hints at coloration and habits, and will probably pass unrecognized by strangers to the land. The letterpress is pleasantly and graphically written, and the illustrations—one in colour the remainder in pencil—are delightful.

Science and Ethics*

By Dr. Edwin Grant Conklin, Princeton University, Princeton, N.J.

IN the early years of the Association, a favourite theme in the annual address of the retiring president was the relation between science and religion. To a majority of modern scientists nothing is more dull and fruitless than attempts to make science the handmaid of theology. But there is an aspect of religion with which science is vitally concerned, namely, ethics, and this has been well called "the religion of science".

Science, as we all know, is tested, verifiable, organized knowledge; ethics pertains to ideals, conduct and character. Any programme looking to human welfare and betterment must include both science and ethics, and there would be a great gain for the world if organized religion and organized science would co-operate more effectively in the promotion of practical ethics.

The differences between the ethics of religion and that of science relate largely to questions of origin rather than of content or purpose. One regards the basis of ethics as supernatural, the other as natural; one derives ethical codes from divine commands, the other from human nature and social utility; one from direct revelation of the divine will, the other from germ-plasm, endocrines and social instincts. But in spite of these differences in origin, the content is essentially the same. Whether written on tables of stone or on the tables of our hearts, the 'cardinal virtues' are still virtues and the 'deadly sins' are still sins. The deepest instincts of human nature cry out for justice, truth, beauty, sympathy. Ethics that is based on the satisfaction of these desires and needs, on the enduring pleasures of the mind, the æsthetic sense, the love and service of one's fellow men, is not different from the ethics of the divine command to "lay up for yourselves treasures in heaven". Ethics which cultivates justice, truth, courage, beauty, sympathy, love is essentially the same in kind as the two great commandments, "Thou shalt love the Lord thy God with all thy heart, and thy neighbour as thyself". The new ethics of science does not differ in content from the old ethics of religion, and the commandments of a God within are no less binding than those of a God without.

Among the generalizations of science which have been charged with the weakening of ethics, first place must be given to the theory of the natural evolution of man and of ethical systems. It is a fundamental postulate of modern science that man is a part of Nature, and that his body, mind and social relations have undergone evolution in the long history of the human species. This is not a mere hypothesis but an established fact. There is positive evidence that in long past times there were types of human and partly human beings that were much more brutish in body, mind and social relations than the general average of the present race. There is abundant evidence that ethics has undergone evolution no less than intelligence; it has developed from its beginnings in the primitive family group, to tribal, racial, national and international relations; from the ideals and practices of savagery to those of barbarism and civilization; from the iron rule of vengeance, "an eye for an eye, a tooth for a tooth", to the ideals of love and forgiveness and that highest conception of ethics embodied in the Golden Rule. But as in physical evolution there are retarded individuals and races, so also in the development of ethical ideals some people are far behind others, and all fall short of their highest ideals.

The fact that ethical codes have differed widely among different peoples and in different stages of culture has sometimes been held to prove that there are no general ethical standards, but that ethical actions are merely those which seem good for me or my class or nation. But the fact that there are narrow and selfish codes of ethics as well as broad and generous ones does not prove that all are of equal value and that there are here no standards of excellence. In the living world there are many grades of organization from amoeba to man, many stages of progress from the egg to the adult, many advances in culture from savagery to civilization, but this does not prove that all these stages are of equal human worth; and the fact that truth, beauty and virtue are relative and not absolute does not mean that ignorance and wisdom are equally good.

As is well known, the distinctive principle running through the whole of Darwin's philosophy of evolution is what he called natural selection. Having studied the notable effects of human selection in the production of new breeds of domestic animals and cultivated plants, he sought for some comparable process operating in Nature without human guidance. This he found in the

---

* Address of the retiring president of the American Association for the Advancement of Science, delivered at Indianapolis on December 28, 1937.

Malthusian principle of over-production of populations, the elimination of the less fit and the preservation of favoured races in the struggle for life. Although he regarded environment, whether organic or inorganic, as being in general the principal eliminator of the unfit, he assigned a certain role to the organism itself as selector and eliminator, especially in sexual selection, while in mental, moral and social evolution this auto-selection played even a larger part in his philosophy.

It has been charged by many humanists that this Darwinism is destructive of the highest ethical ideals. It is said to be the apotheosis of cruelty and selfishness, to recognize no values except survival, no ideals except success. In this struggle for existence, the weak go under, the strong survive. Militarists and dictators have seized upon this principle as justification of their philosophy that might makes right. Conflicts and wars are said to be both the means and measure of progress, and military training to be the highest type of discipline.

This is, however, a fundamental misconception of natural selection. Darwin himself repudiated this extension of his principle to the struggle between races and nations of men. Those who attempt to extend it into the field of intellectual, social and moral qualities should remember that the standards of fitness are wholly different in these fields. Physically, the fittest is the most viable and most capable of leaving offspring; intellectually, the fittest is the most rational; socially, the fittest is the most ethical. To attempt to measure intellectual or social fitness by standards of physical fitness is hopelessly to confuse the whole question, for human evolution has progressed in these three distinct paths. Man owes his unique position in Nature to this three-fold evolution, and although the factors of physical, intellectual and social progress are always balanced one against another, they are not mutually exclusive.

This leads to the inquiry whether human, or so-called artificial, selection is not also natural. If we define 'natural' as that which is regular and lawful, and not arbitrary and lawless, then human selection is also natural. The study of the behaviour of lower organisms, as well as that of human beings in all stages of development from the infant to the adult, has shown that selection is everywhere taking place. One-celled plants and animals, for example, avoid extremes of heat or cold, move or grow toward certain chemical substances and away from others, take in as food certain substances and reject others. Even germ cells show some of these same properties, and in general it may be said that all living things manifest differential sensitivity and reactivity, and that by a process of trial and error and finally trial and success they generally manage to eliminate reactions that are not satisfactory and to persist in those that are. This is the Darwinian principle extended to the reactions of organisms in which the organism itself is eliminator and selector.

Intelligence in animals and man is arrived at in this same way, by many trials and failures and finally trial and success, remembering of past failures and successes, elimination of the former and persistence in the latter A cat that by trial and error has learned to open the door of a cage, or a horse that has learned in the same way to lift a latch and open a gate, is intelligent with respect to that one situation; intelligence in human beings is acquired in the same way. Indeed, intelligence is the capacity of profiting by experience, while the ability to generalize experiences is what we call abstract thought, or reasoning.

In his famous Romanes Address in 1892 on "Evolution and Ethics", Prof. T. H. Huxley maintained that ethics consists in opposing the cosmic process of natural selection by intelligent human selection, and in replacing the ruthless destruction of the weak and helpless with human sympathy and co-operation. He illustrated the superiority of human selection by pointing out the fact that a cultivated garden left to Nature grows up to weeds and, therefore, that human intelligence can improve on the blind processes of Nature in meeting human needs.

All this is undoubtedly true; we are continually improving on Nature for our own purposes; all agriculture, industry, medicine, education are improvements on Nature. The notion that Nature is always perfect is certainly false, and the cry, "Back to Nature", is more likely to be a call to regress than to progress. But it is a mistake to suppose that human intelligence and purpose, social sympathy, co-operation and ethics in general are not also parts of Nature and products of natural evolution. In Darwin's theory the environment eliminates the unfit individual, but in individual adaptations to new conditions the organism itself eliminates many useless or injurious responses. In such cases the organism rather than the environment is the eliminator or selector, either by the hit or miss process of 'trial and error', or by the vastly more rapid and less wasteful method of remembered experience, that is, by intelligence. Thus intelligence can improve on the blind processes of Nature, because it is not blind, although it also is natural; and thus intelligence has become a prime factor in evolution.

It is clear that social ethics assumes the ability and the responsibility of individuals to regulate behaviour in accordance with ideals and codes of conduct. It therefore demands freedom to choose between alternatives that are offered. Without such freedom there can be no responsibility, no duty, no ethics. It has long been the creed of certain rigidly mechanistic scientists that freedom, responsibility and duty are mere delusions, and that human beings are automata, thinking, feeling and doing only those things which were predetermined by their heredity and environment over which they have no control This fatalistic creed was in large part a deduction from the determinism of Nature which was revealed in mathematics, astronomy, physics and chemistry, and was then extended by certain physiologists to all vital phenomena, including human life and personality Indeed, some of these 'hard determinists' went so far as to maintain that the whole course of human history was predetermined in the original constitution of the universe, that nations had risen and fallen, cultures and civilizations had come and gone, and that the present state of the world and its future destiny were all determined by inexorable laws. However, many biologists who investigated the behaviour of animals refused to regard them as mere automata, and students of human behaviour generally held that there must be some flaw or break in this logical chain that bound man helpless on the wheel of fate, some fallacy in the logic that denied him all freedom and responsibility, some monstrous error in the conclusion that saints and sinners, philanthropists and fiends were mere pawns or puppets in a game in which they were moved by forces over which they had no control.

The 'closed universe' of physical science is strangely unlike the world of human experience, but its adherents argue that experience is subject to delusions from which rigid logic and genuine science are supposed to be exempt. In such a 'closed universe' man does only what he is compelled to do; there is no freedom, responsibility or duty, no place for purposive education, ethics or religion.

As a way of escape, mathematicians and physicists, who were most impressed by the determinism of inanimate Nature, were generally inclined to adopt some form of Cartesian dualism, which would endow living beings, and especially man, with an unmaterial principle or soul which was not subject to this rigid determinism. But, on the other hand, students of life phenomena in general could find no sufficient evidence for such dualism, and hence arose the strange anomaly of physiologists and psychologists becoming more rigid determinists, so far as life and man are concerned, than students of the physical sciences.

Several scientists have expressed the view that Heisenberg's principle of indeterminacy in the subatomic field can somehow be converted into the novelty, creativity and freedom manifested by living things. But no one has shown explicitly how this can be done. Furthermore, biologists generally do not admit any fundamental indeterminacy in the behaviour of living beings. Novelty, creativity and freedom, wherever their origin has been traced, are found to be caused by new combinations of old elements or processes, whether these be atoms, molecules, genes, chromosomes, cells, organs, functions, or even sensations, memories and ideas. By such new combinations of old elements there emerge all the new properties of chemical compounds, and by new combinations of genes and chromosomes and environmental stimuli all the novelties of heredity and development arise. There is good evidence that even psychical properties, such as consciousness, intelligence and will, emerge in the process of development because of specific combinations of physical and psychical factors. This is, indeed, the whole philosophy of evolution; namely, that the entire universe, including man and all his faculties and activities, are the results of transformation rather than of new-formation, of emergence rather than of creation *de novo*.

Freedom does not mean uncaused activity; "the will is not a little deity encapsuled in the brain", but instead it is the sum of all those physical and psychical processes, including especially reflexes, conditionings and remembered experiences, which act as stimuli in initiating or directing behaviour. The will is not undetermined, uncaused, absolutely free, but is the result of the organization and experience of the organism, and in turn is a factor in determining behaviour. Therefore, we do not need to import from subatomic physics the uncertain principle of uncertainty in order to explain free will. The fact that man can control to a certain extent his own acts as well as phenomena outside himself requires neither a little dæmon in the electron nor a big one in the man.

Just one hundred years ago Wordsworth wrote:

> "Man now presides
> In power where once he trembled in his weakness;
> Science advances with gigantic strides,
> But are we aught enriched in love and meekness?"
> (Miscellaneous Sonnets, Part 3, 41, Jan. 1838.)

These lines are much more significant to-day than when they were penned, for so far as our knowledge of and control over natural forces and processes are concerned, we live in a new world.

"But are we aught enriched in love and meekness?"

Neither in human nature nor in social relations has progress kept pace with science. This is not the fault of science but rather of man and of society. The great advances in the applications of science have often been used for selfish purposes rather than for social welfare. Scientific progress in medicine and sanitation is far in advance of its social utilization, but not in advance of its urgent need. Rational and peaceful means of solving class conflicts and of preventing wars would be vastly less costly and more effective than strikes and armaments. The fact is that social progress has moved so much slower than science that one might say that scientific progress is matched against social stagnation. Many thoughtful persons are asking: "Will science, which has so largely made our modern civilization, end in destroying it?"

A fundamental fact is that improvements in human nature are not keeping pace with increasing knowledge of and control over outer Nature. By means of language, writing, printing, the radio, and all the means of communication and conservation of knowledge, each human generation transmits its accomplishments to succeeding ones.

Thus present science, culture and civilization represent the accumulated experience and knowledge of all the past, each succeeding generation standing, as it were, on the shoulders of preceding ones. Every individual, on the other hand, begins life where all his ancestors began, namely, in the valley of the germ cells; he then climbs to the summit of maturity and goes down into the valley of death. But society, gifted with continuous life, passes on with giant strides from mountain top to mountain top; and so it happens that science and civilization in general outrun individual heredity, for the learning and acquirements of each generation are not transmitted to succeeding ones through the germ cells but only through social contacts. For this reason increasing knowledge and power have greatly outrun improvements in inherent human nature.

What is the remedy, if any, for the lag in the progress of human nature behind the progress of science and society? Eugenics has been proposed as a possible and necessary solution of this problem. Undoubtedly great improvement in human heredity could be effected if the principles of good breeding which are used with such notable results in the improvement of domesticated animals and cultivated plants were to be used in the breeding of men. There is no doubt among students of heredity that by means of a system of selective breeding a healthier, longer-lived, more intelligent, more emotionally stable human type could be developed. But the difficulties in the way of such a eugenical programme are enormous where the human stock is so mixed, as it is in almost all races of men, and where the rules of good breeding would have to be self-administered or imposed by authorities that are influenced by social, racial or ethical prejudices. Even if these obstacles could be overcome and this programme wisely and persistently followed, it would take thousands of years to bring about any marked improvement in the masses of mankind.

Fortunately there are other and more rapidly acting remedies for this disharmony between social progress and biological inheritance. Heredity determines only the capacities and potentialities of an organism; the realization of those potentialities depends upon development, which is greatly influenced by environment, hormones, health or disease, use or disuse, conditioned reflexes or habits. In every individual there are many capacities that remain undeveloped because of lack of suitable stimuli to call them forth. Since these inherited potentialities may be social or antisocial, good or bad, it is the aim of enlightened society to develop the former and to suppress the latter. In the heredity of every human being there are many possible personalities; which one of these becomes actual depends upon developmental stimuli. Each of us might have been much better or much worse than we are if the conditions of our development had been different. Endocrinologists and students of nutrition are already preventing or overcoming many of the deficiencies or defects that arise in the course of development. In these respects science is contributing greatly to human welfare and to practical ethics.

But of all the possible means of rapidly improving social conditions, ethical education is probably the most promising. Indeed, education, based on a knowledge of the principles of development and aimed at the cultivation of better relations among all classes, races and nations, is the chief hope of social progress.

The most enduring effect of education is habit formation. Good education consists in large part in the formation of good habits of body, mind and morals. Heredity is original or first nature; habits are second nature, and for character formation and social value they are almost as important as heredity itself. To trust entirely to heredity to improve men or society is to forget that heredity furnishes capacities for evil as well as for good, and to disregard the universal experience of mankind that human nature may be improved by humane nurture.

On these grounds certain humanists have proposed that art, literature, history and political and moral philosophy should replace science in the educational programme, since, as they assert, science, being materialistic, non-ethical and lacking in high ideals, neglects or destroys the real values of life. The president of the University of Chicago has recently called science a failure in the educational process, and he urges a return to philosophy as the only sure road to sound discipline and true culture. Those who have never experienced the discipline and ennobling effects of scientific studies fear that science will destroy our civilization, and are calling upon educators to repent and to return to the good old subjects of classical learning. Without discussing the subject in general, it may be remarked that it was not science that caused the decay of former civilizations, nor was it in the power of classic art, literature and philosophy to save those civilizations. Certainly there are no other studies than science that distinguish so sharply truth from error, evidence from opinion, reason from emotion; none that teach a greater reverence for truth or inspire more laborious and persistent search for it. Great is philosophy, for it is an attempt at a synthesis of all knowledge, but if it is true philosophy it must be built upon science, which is tested knowledge.

> "To the solid ground of nature
> Trusts the Mind that builds for aye."

Education, then, which looks to the highest development of the physical, intellectual and moral capacities of men is the chief hope of human progress. Even any possible programme of improvement of inherited human nature must rest upon education concerning the principles of heredity and the methods of applying them to the breeding of men. Without waiting for the slow improvement of human nature through eugenics, great progress can be made toward the 'good society' by the better development of the capacities we already possess. As a matter of fact, all of the great advances from savagery to the highest civilizations have been made without corresponding improvements in heredity.

Although our inherited capacities have not greatly increased since our progenitors rose out of barbarism, yet there has grown up within us an increasing respect for the human mind and a deep conviction of the importance of its freedom. We who are the inheritors of the tradition of liberty of thought, speech and press, and who believe that freedom and responsibility are essential to all progress, should use our utmost influence to see that intellectual freedom shall not perish from the earth. Such freedom has been essential for the advance of science, and the time has come when science should stand for freedom, especially in those countries where force, war and unutterable ferocity are used to compel acceptance of political, social or scientific creeds.

There is no possibility that all men can be made alike in personality, nor any reason why all races and nations should hold the same political and social ideals. But there are good grounds for hoping that they may come to cherish the same fundamental ethical concepts; for the needs and satisfactions, the instincts and emotions of all men are essentially similar. Science is everywhere the same in aims and methods, and this fact greatly strengthens the hope that in a world bound together by science into one neighbourhood there may come to be common ideals regarding fundamental ethics. The greatest problems that confront the human race are how to promote social co-operation; how to increase loyalty to truth, how to promote justice, brotherhood; how to expand ethics until it shall embrace all mankind. This is a problem for science as well as for government, education and religion. Each of these agencies has its own proper functions to perform.

The ethics of science regards the search for truth as one of the highest duties of man; it regards noble human character as the finest product of evolution; it considers the service of all mankind as the universal good; it teaches that both human nature and humane nurture may be improved, that reason may overcome unreason, co-operation supplement competition, and the progress of the human race through future ages be promoted by human intelligence and purpose.

In its practical aspects the ethics of science includes everything that concerns human welfare and social relations; it includes eugenics and all possible means of improving human heredity through the discovery and application of the principles of genetics; it is concerned with the best means of attaining and maintaining an optimum population; it includes all those agencies, such as experimental biology and medicine, endocrinology, nutrition and child study, which promise to improve bodies and minds. It includes the many scientific aspects of economics, politics and government; it is concerned especially with education of a kind that establishes habits of rational thinking, generous feeling and courageous doing.

In spite of notable advances of our knowledge of these subjects, we still know too little about human nature and the causes of social disorders. The extension of the methods of experimental science into their study is bound to be one of the major advances of the future, as it has in the field of medicine since the days when human ills were thought to be due to demons. The ills of society have natural causes and they can be cured similarly by controlling those causes.

It has always been true and will continue to be true that knowledge outruns practice and that ideals are better than performance. How can men be induced to live up to the best they know? How can they be brought to substitute the spirit of service for selfishness, love for hate, reason for unreason? The long efforts of past centuries show that there is no rapid solution of this great problem. But in the co-operation of science, education and religion there is hope for the future.

Mineral Resources of the East Midlands

A JOINT discussion between Section C (Geology) and Section E (Geography) of the British Association on the "Potential Mineral Resources of Nottinghamshire and Lincolnshire and their Geographical Significance" was held on September 6. The region discussed included the whole of Nottinghamshire and Lincolnshire, and a wedge of Leicestershire which penetrates northwards between the two counties. Owing to geographical barriers on the north and south, this region has always been isolated from the rest of England. Even to-day, it is still practically unaffected by those great industrial movements which are elsewhere changing the aspect of the English lowlands.

The distribution of mineral resources in this region is dependent upon its geological constitution and structure. The newer rocks which occupy its surface range in age from the Permian to the Cretaceous. They dip gently eastwards and have experienced no appreciable disturbance. Their outcrops occupy broad belts of country which trend north and south, and give rise to scarplands and clay plains having a corresponding arrangement. The older rocks, which underly the newer, belong mainly to the Carboniferous system, and include a large extent of productive coal measures. They have been much disturbed, and suffered severe denudation before they were covered up by the later rocks.

Though coal and iron exceed all other minerals in importance, attention was first given to certain minor mineral resources which are essential to the development of any area where coal and iron are being exploited. This region is amply provided with such accessory minerals for the erection of buildings and the making and maintaining of roads. Whilst nearly half the region has good underground reserves of water, the problem of water supply is still unsolved for the great clay plains.

Turning to the two vital minerals, it was brought out in the discussion that, whilst the Derbyshire margin of the coal-field has been exploited for seven centuries and is approaching exhaustion, the Nottinghamshire field, though still in its infancy, has already become the most productive and economically worked field in England. Lying as it does in a basin that is largely hidden under a covering of newer rocks, its future development will be governed by several natural factors. First must be mentioned the regular increase of thickness of the newer rocks as they dip eastwards. This already attains a total of 3,000 feet east of Lincoln. Secondly, it has always been known that the coal measures under west Nottinghamshire dip eastwards. The Coal Commission of 1871 did not venture to extend that dip beyond the line of the River Trent, and therefore gave that as the eastern limit of the field. The Commission of 1905 took a rosier view and shifted the boundary to Boston. In 1925 the Geological Survey, basing its view upon the records of subsequent borings, returned to the opinion of the 1871 Commission; for they found that, under east Nottinghamshire, the eastwards dip was being reversed, and that the rate at which the seams were rising pointed to an early disappearance of the Coal Measures in that direction.

At this point in the discussion Dr. D. A. Wray, of the Geological Survey, roused considerable interest by making a most important statement embodying the results of still more recent borings, including one which had been recently put down near Lincoln. It seems that the measures rise less rapidly eastwards than had been thought, and that a considerable thickness of coal measures has been proved to underly west Lincolnshire. He revealed, however, a third and unsuspected adverse factor in the behaviour of the Upper Red Measures. These non-productive beds not only thicken eastwards but also pass unconformably across the bevelled edges of the productive measures, so that the latter cannot extend much farther east than Lincoln. Nevertheless, the net result of the fresh information, thus divulged for the first time, is that the extent of the proved coal-field has been increased by 50 per cent.

In considering the iron resources of the region, emphasis was laid upon the fact that the greatest reserves lie either at the extreme north, around Scunthorpe, or beyond the southern boundary, around Corby. Reference was also made to considerable reserves recently discovered in the southern end of the Lincolnshire Wolds.

In discussing the geographical significance of the geological information which had been supplied, attention was first given to industries associated with the accessory minerals. These are small and scattered. Dealing with transport, it was shown that the network of roads and railways form a close mesh over west Nottinghamshire but become a much wider mesh towards the east. East and west movement have always been impeded by the existence of several north-to-south barriers, of which the Trent has proved to be the most serious.

The close relationship of the overcoming of this barrier to industrial development was illustrated by the building of the Keadby bridge in 1861 and its enlargement in 1916, which was followed immediately by the rapid growth of the iron-works at Scunthorpe and Frodingham.

Discussion of the major minerals was limited to the iron industry. Since this requires a complicated and very costly plant, as well as labour skilled in the handling of hot metals, it was considered unlikely that the future would bring the development of any new centres; but that, on the contrary, there would be a further concentration of the industry at Scunthorpe and Frodingham in the north and at Corby in the south. Though the prophets disagreed concerning the more distant future of these centres, they were unanimously of the opinion that their prosperity is guaranteed by their resources for many years.

In view of these facts, and of the stationary or possibly declining population of Great Britain as a whole in the coming years, it was concluded that little or no redistribution of population would follow the future exploitation of the resources of the region under discussion. It may be pointed out here, however, as a remarkable oversight, that the geographical effects of the exploitation of the coal were not discussed, for the factors which control this compel the establishment of many new centres of industry, of many new lines of transport, and a large scattering movement of population.

H. H. S.

The Scientific Delegation in India

From a Correspondent

Darjeeling, December 30, 1937.

IT will be remembered that the great majority of the scientific delegation to India arranged by the British Association at the request of the Indian Science Congress Association, left England on the S.S. *Cathay* at the end of November. Their voyage could scarcely have been more prosperous; evidently heavy weather was just escaped, and only one rather rough night, when the ship was nearing Marseilles, caused a measure of complaint; while an unexpectedly strong southerly wind in the Red Sea kept the temperature tolerable. After arrival in Bombay, the party entered upon a whirl of entertainment, sight-seeing, and travel. Every possible opportunity, however, was given and taken for conversations in matters of common scientific interest between individual visitors and residents; old acquaintances were renewed, new contacts made. Lectures and broadcasts have been given at various points, and have been received with every manifestation of interest. The reception accorded to the party has everywhere been cordial in the extreme, and the enjoyment of a wonderful journey has been complete, save for the cases of slight indisposition apparently inseparable from any visit of a party of newcomers to India, and for two major causes of general regret. One of these has been the enforced return of Dr. A. B. Rendle to England from Bombay, owing to ill-health. The other has been the serious accident to Dr. W. W. Vaughan, who in darkness at the Taj Mahal fell and sustained a compound fracture of a leg.

At Bombay, the University entertained the party. In Hyderabad State all were guests of the Government throughout the sojourn, which included entertainment, inspection of the new Osmania University, visits to the forts of Golconda and Daulatabad and the rock-hewn temples of Ellora and Ajanta, and all the transport entailed, both by rail and road. At Agra, the Taj Mahal, the fort, and Fatehpur-Sikri were seen, and it is worthy of record that both here and elsewhere such world-famous monuments have at least equalled, if not exceeded, the visitors' preconceptions of them. The Latitude Variation Observatory and the Meteorological Station at Agra, and the Moslem University at Aligarh, were viewed by those specially interested. At Delhi, on Christmas Eve and Christmas Day, the party was splendidly entertained by the Government of India and by private individuals, and a fleet of cars provided by the Government facilitated visits to points of interest. At Dehra Dun, the Forestry Research Station and the Geodetic Survey Department were thoroughly investigated, and, the weather proving kind, nearly all the party drove up to the ridge of Mussoorie, from which most of them enjoyed their first view of Himalayan snow-peaks. A few individual members diverged from the main route to visit points of special interest to them.

At Benares the whole party was entertained by the Hindu University, and attended a convocation there, a brilliant ceremony at which honorary degrees were conferred on the president—Sir James Jeans—and others. The famous river-frontage of the city on the Ganges was viewed from boats, and many of the party found perhaps their greatest satisfaction in wandering among the lively and infinitely picturesque streets of the Indian city.

It had been ascertained during the voyage that for a very large proportion of the party Darjeeling was the Mecca of the tour, and it was accordingly requested by wireless, and duly arranged, that the special train should proceed to Siliguri, the terminus for the mountain road and railway, after a short halt at Calcutta, where there was time for no more than a few personal introductions, and for taking temporary leave of Prof. J. N. Mukherjee, who had accompanied and guided the party from Bombay, and to whom every member owes gratitude beyond expression.

It is from Darjeeling that this note is written. The weather, perfect throughout the tour, has favoured us to-day beyond conception: the famous views from the town and from Tiger Hill, of Kangchengjunga and its satallite range, of Makalu, of glimpses of Everest vouchsafed to some through a cloak of cloud, have reached their most splendid standard, and the half cannot be told of them. The party has to-morrow here for rest, and then returns to Calcutta for the Congress next week.

Obituary Notices

Prof. H. Molisch

HANS MOLISCH, whose death at the age of eighty-one years took place on December 8, was born in Brünn in 1856, the son of an intelligent and progressive nurseryman, who employed his son in his early years in his business, so that from his boyhood Molisch became interested in plants, and already when at the Grammar School in Brünn he distinguished himself by his botanical knowledge. His enthusiasm for the subject may have been further fired by his knowledge of the experimental plant-breeding which was being carried on in Brünn by the Abbé Mendel, who was a friend of his father. At any rate, when he entered the University of Vienna in 1876, he had already made up his mind to become a botanist, and in his autobiography, which was reviewed in NATURE of September 28, 1935, p. 494, he speaks with enthusiasm of his teacher, Julius Wiesner, and also of many kindnesses he received from Kerner von Marilaun, the director of the Botanical Gardens.

Molisch's doctor's degree was awarded to him for a thesis on the anatomy of the wood of the Ebenaceæ, and he was then appointed assistant to Prof. Wiesner, a post which he retained until 1889. Whilst acting as assistant, he became *Privat dozent*, and his lectures, which dealt with plant physiology, were always well attended. In 1889 he was appointed to a professorship in the Technical College at Graz, and in 1894 to the German University of Prague. While occupying the former position he published his histochemistry of vegetable foods and an important physiological study entitled "Die Pflanze in ihren Beziehungen zum Eisen", in which he showed that the chlorosis induced by growing plants in a medium devoid of iron is not a direct result of the absence of that element, but is the symptom of a pathological condition induced by lack of iron, for by sensitive microchemical tests, in which he always excelled, he proved that chlorophyll itself does not contain iron. After his promotion to Prague, he devoted some attention to the lower forms of plant life, stimulated in part by a request to investigate the microflora of the water supply of Prague, which was at that time of a very impure nature. In this way he became interested in the phosphorescent bacteria and other fungi, of which he published an account, and also made important discoveries in connexion with the nutrition of Algæ. But he also continued to work on the anatomy of plants, particularly on the laticiferous tissues, and studied microscopically the phenomena associated with the freezing of vegetable tissues. In 1897 he undertook a botanical tour into the tropics, spending some time on physiological investigations in Buitenzorg and returning via China, Japan and America.

On the retirement of Prof. Wiesner in 1909, Molisch was appointed to the chair of plant physiology in the University of Vienna, which he held until 1928, when on retiring he was made emeritus professor. During this period, he received an invitation to take charge for three years of the newly established Biological Institute of the University of Tôhoku in Japan and was granted leave of absence for three years for this purpose by the University of Vienna. This Eastern visit, and a subsequent invitation to lecture and work at the Bose Institute in Calcutta, widely extended his opportunities for observation as one can readily see in his "Lebensdauer der Pflanze" (1929), in which plants from many lands are discussed.

In a more recent book, "Pflanzenchemie und Pflanzenverwandschaft" (1933), Molisch took up again what he admits was his favourite study, the microchemistry of plants, this time with a view of ascertaining what connexion exists between the chemical composition of plants and their relationship.

In all his studies, Molisch never lost sight of the applied side of botany, and his early horticultural training led him to write in 1915 a most useful "Plant Physiology as a Theory of Horticulture", which has passed through six editions and has been translated into several languages. When we consider the multiplicity of subjects which have engaged his attention, we realize that Molisch possessed an eager and inquiring mind constantly seeking for the solution of problems which presented themselves to him, working unremittingly and rapidly, and that he was able to present the results of his investigations with clarity and in forceful language. He remained active to the end, and so recently as 1937, when in his eightieth year, he published a striking series of experiments under the title "Der Einfluss einer Pflanze auf die andere".

By Molisch's death botany has lost a veteran who has enriched botanical science not only in the domain of plant physiology, in which he was one of the foremost workers, but also, as the record of his numerous books indicates, one who was a capable investigator in many other directions.

WE regret to announce the following deaths:

Prof. N. A. Borodin, emeritus curator of fishes in the Harvard Museum of Comparative Zoology, on December 22, aged seventy years.

Mr. W. B. Grove, formerly honorary curator of the Fungus Herbarium in the University of Birmingham, on January 6, aged eighty-nine years.

Dr. A. B. Rendle, F.R.S., formerly keeper of the Department of Botany in the British Museum (Natural History), on January 11, aged seventy-two years.

Mr. J. L. Starkey, director of the Wellcome-Marston Expedition excavating at Tell Duweir, on January 10.

Prof. Otto H. Warburg, For.Mem.R.S., director of the Kaiser Wilhelm Institut fur Zellphysiologie, on January 11, aged fifty-four years.

News and Views

Science and Social Problems

WE recorded last week (p. 69) the formation of a National Institute of Economic and Social Research, one of the functions of which will be scientific inquiry into the facts and problems of contemporary human society. The committee which has had this development under discussion since last March includes leading representatives of various aspects of economics; but we miss the names of scientific workers in the wider field of social biology, or with intimate knowledge of the forces which are chiefly responsible for the problems involved in the changed and changing social structure of all civilized peoples. Two statements on the interaction between science and society may be used to illustrate what we have in mind. One is an address given by Prof. H. Levy on December 13 at a meeting called by the Manchester Scientists Peace Association. He pointed out that men of science and their pursuits are a part of society and that the results of their work do not affect society more certainly than the nature of society itself determines the nature and extent of their own investigations. Prof. Levy's address was in the main concerned with the scientific and objective study of problems of peace, and he urged the claims of the scientific man to a greater share in administrative responsibility. His argument is, however, essentially similar to that of Prof. J. Marrack in his thought-provoking essay on the social implications of biochemistry, contributed to the volume of essays "Perspectives in Biochemistry" which was presented to Sir Frederick Gowland Hopkins by past and present members of his laboratory on his seventy-fifth birthday. Prof. Marrack points out that the future trend of biochemical investigation in problems of nutrition depends largely on what form society takes. It is only as a result of the biochemical work of the last thirty years, the discovery of vitamins and the later investigations of mineral and protein requirements that it has become possible to draw up diet standards. From this fundamental knowledge, the conclusion is reached that the health of a large proportion of the people of Great Britain would be improved by a better diet and that the adequacy of a family's diet depends on the family income.

CONTINUANCE of the present interest in the study of deficiencies may provide the level of scientific and economic development which makes the study of such problems practicable, and the impact of biochemistry on society may result in an economic diet standard based on the principle of the law of diminishing returns. Instead of social services being expanded to ensure that such a diet can be obtained by all, our present social system may equally lead to a collapse with even more examples of food deficiency, and perhaps destroy the environment necessary for their study. Prof. Marrack suggests, however, that a society which took as a major objective the use of all possible resources to increase the material welfare of the people would aim at the physiological optimum, and investigation would be transferred from the negative object of avoiding disease to the positive object of using an abundant food supply to achieve a new standard of health and vigour. To the provision of this abundance, biochemistry can make its own contribution, and Prof. Marrack refers also to the way in which the study of the hormones offers man the possibility of controlling his environment to suit his wishes. The sense of power over Nature which the growing knowledge of biochemistry supplies should gradually give all men the confidence to shed traditional beliefs and inhibitions and to shape a society in which all the possible resources of science and production are used for the common good.

Evolution and Ethics

NEARLY half a century ago Prof. T. H. Huxley, in a brilliant lecture on "Evolution and Ethics", pointed out that the view that Darwinism signifies nothing more than striving after personal or national mastery at all costs is a crude misconception of this great principle. The evolution of man himself embodies not only his physical structure but also all other attributes which have made him what he is: it involves the progressive development of standards of personal and social ethics and makes the welfare of the human race the highest purpose of the life of the individual and of the community. Material progress is only one aspect of such development, and the world is being reminded every day that it can be used as a destroying agency as well as a civilizing influence. In spite, however, of these prostituted activities, it must be acknowledged that the advance of science has, on the whole, led to the alleviation of human suffering and an increase in the capacity and the facilities for happiness. Any action—whether in peace or war—which makes degrading uses of scientific discovery and invention should be condemned by all who believe that in the evolution of man other factors are involved than those of the race to the swift and the battle to the strong. Prof. Conklin makes a most eloquent plea for the understanding of this high mission of science in the address on "Science and Ethics" delivered before the American Association for the Advancement of Science and published in the present issue of NATURE. The social aspects of scientific teaching and principles were also the subject of an address on "Science and Citizenship" delivered before the Science Masters' Association on January 5. It is only by action in the spirit of these addresses that we may hope for, or expect, any advance in the ethical evolution of man himself or of civilization, which is the expression of his activities.

The Services of Engineering to Mankind

NEARLY a century ago, Dr. Samuel Smiles realized the fundamental importance to civilization of the work of the engineer and correctly estimated the interest it must have for the public. In explaining his books he wrote, "Our engineers may be regarded in some measure as the makers of modern civilisation", and he records that in a letter to him Cobden wrote, "it cannot be doubted that each succeeding generation will hold in higher estimation those discoveries in physical science to which mankind must attribute henceforth so largely its progress and improvement". These views are brought to mind by the announcement made as to its aims by the Engineering Public Relations Committee, which has recently been formed on the initiative of the Institution of Civil Engineers acting in conjunction with the leading engineering organizations in London, with Sir Clement Hindley as its first chairman. Its function is to present to the public, in suitable form, information concerning the science and practice of engineering and its service to civilization. Through the ordinary channels of information, prominence is given to the spectacular side of such undertakings as the building of the *Queen Mary*, the construction of the Mersey Tunnel and that of the Sydney Harbour Bridge, to mention only three great works of the last few years, but this treatment tends to obscure from public view the knowledge of the ceaseless efforts being put forth to understand more fully the works of Nature and so to harness them to the service of mankind. It is only thus that such vast undertakings can be attempted with prospect of success.

IMPROVEMENTS in the manufacture of iron and steel and other materials and in the methods of using these products to meet the changing needs of the time, advances in the design and construction of engines and machine tools, new applications of electric, hydraulic and pneumatic energy and of the refrigerating principle are but a few of the lines on which advancement is being made. At the present time, it would appear that an era of the importance of alloy metals is beginning; by their means combinations of properties are being obtained such as open up new possibilities for the engineer. With the extension of the use of metals, more and more of the work of the world comes within his province, and it is therefore most desirable that the accomplishments, purposes and possibilities of the several branches of engineering should be more fully and more generally understood. The Committee proposes by means of lectures for schools and colleges, by exhibitions, and by co-operation with the Press, the British Broadcasting Corporation and the news film companies, to get into touch with the public. Efforts will also be made to work in conjunction with engineering societies outside London and with all bodies interested in engineering. The secretary and public relations officer is Lieut.-Colonel F. H. Budden, whose address is at 1–7 Great George Street, S.W.1.

Selection for Post-Primary Education

DR. W. P. ALEXANDER gave a paper at a meeting in connexion with the recent conference of the National Union of Teachers to members engaged in higher education, on "Methods of Selection for Post-Primary Education". He emphasized the need for basing any system of selection on the capacity of the pupils to profit by the type of education to be followed. As at present arranged, selection is based rather on good work done in the junior school, instead of on the grounds of the child's capacity to profit by the education offered. The first most important factor is general mental energy, expressing itself primarily in words, and this ability should be the basis of selection for the grammar school type of education, or in terms of things, showing itself as practical or technical ability. In addition, however, there is required for success in life the character quality of determination. How these requirements are to be tested is a matter for research, some at least of which has already been done. Dr. Alexander suggested that the first selection need only be very simple tests in English and arithmetic, in order to know if the child has sufficient facility to begin post-primary education. For the second selection we need tests to measure general mental energy in conjunction with verbal ability or with technical ability. Lastly, in the absence of reliable tests for character qualities, the considered opinions of the school staff could be utilized. Not only would this method be simpler than the one now in operation, but it would also free the primary schools from the examination fetish. Having ascertained how many pupils there are who have the capacity to profit by the grammar school or advanced technical instruction, the necessary facilities must be provided. For the others, senior modern schools with sufficient variation to allow for the varying degrees and types of capacities among the pupils are needed.

Research of the Royal College of Surgeons

THE scientific report of the Royal College of Surgeons of England for the past year reveals the extraordinary diversity of work which is being carried out in the Museum, Research Laboratories and the Buckston Browne Surgical Research Farm, in spite of the fact that work has been severely handicapped by a rebuilding programme which will give the College of Surgeons a unique research unit. There has been great activity in almost every field. In the Museum, the Pathological Curator reports considerable progress in the renewing of the pathological series, and in the fields of physical anthropology there have been large accessions of human material from archæological excavations in Great Britain and abroad. As for the purely research activities of the College, these have been carried on, although under difficult conditions, in temporary laboratories at St. Bartholomew's Medical School and at the Buckston Browne Research Farm. To mention only a few of the outstanding investigations which have been pursued in the course of the year, great progress has been made in the development of operative technique for the treatment of certain forms of heart disease, technique which has been most successful in its clinical applications. Work on the physiology of the urinary system has done much to solve the problem of the nervous control of the pelvis and ureter. Experimental research on nerve grafting, begun the previous year, has been continued, and is producing results which are of the greatest interest. Of particular importance from a practical point of view is the work on high blood pressure, which disease has been reproduced in the experimental animal, and has been found to resemble closely in its clinical features and histology arterial hypertension in the human. A fundamental problem which has been tackled is that of the relation of the central nervous system to carbohydrate metabolism and heat regulation, and we look forward with considerable interest to the further fruits of these investigations.

Publications of the Linnean Society

THE first part of the *Proceedings of the Linnean Society* for the 150th session (1937–38) has appeared. It contains the *acta* of the Society at meetings from that of October 28 to that of December 9; it embodies in full three of the papers read at the meetings, and abstracts of the others, whether reserved for printing in the *Journal* of the Society or not. It is exactly a hundred years since the Society began to print the *Proceedings*. At first they appeared two to five times during a session, in sheets of eight or sixteen pages, by which method during the ten years 1838–1848 the average interval between the making of a communication to the Society and its record in print was six months; and during the seven years 1848–1855 it was seven months. In 1856 the Society began to issue its *Proceedings* of an entire year after the end of the session and continued to do so for seventy-four years, except that between 1860 and 1872 they appeared each year in two, three or four parts as ready.

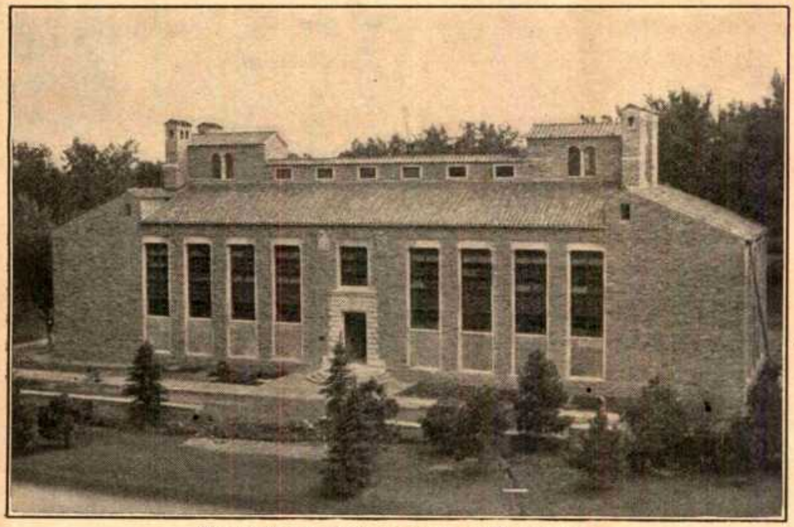
In 1930, the Society reverted to publication by sheets, issuing sixteen pages together or multiples of sixteen. There were nine parts containing the *acta* of the session 1930–31; but, as this entailed excessive charges for postage, the parts were enlarged in order to reduce their number so that they were in the successive years six, five, four and five. In 1935 it was determined that four should be the number of parts in each year; and so it remains. The part just issued is the first part for the session 1937–38. The interval between the reading of the first paper recorded in it and its appearance from the press has been only two months. Slight changes have been made in the format by the use of bold type and spacing so as to make the record fall conveniently into chapters, and to lead the reader quickly to what he wishes to find. The Society is to continue its endeavour to obtain an attractive, as well as a prompt, publication.

Safeguards Against Interruptions of the Electric Supply

THE public and industry now use electricity so largely that any interruption in the continuity of the supply is a serious matter which needs careful consideration. Two factors that accentuate this need are first the increasing growth and interconnexion of generating plant, leading to increased risk of serious damage on the occurrence of a fault, and secondly the increasing tendency to faults occasioned by the extended use of overhead lines for long-distance interconnexion and for supplying rural areas. In a paper on this subject read to the Institution of Electrical Engineers on January 6 by H. W. Clothier, B. H. Leeson and H. Leybourn, a full statement of the problem is given, and the best way of countering the risks run are considered for the various methods of supply. Particulars are given of high-speed small-oil-volume switches capable of breaking the circuit by utilizing in improved ways well-tried principles, and of an automatic reclosing 132 kilovolt oil circuit-breaker with an arc-duration of only one cycle of the current at full rating. It is claimed that when a fault has developed in a component of a supply system provided with protective safeguards of the automatic instantaneous protection type and fast-acting circuit-breakers, very little damage if any is done to the faulty component and there is practically no interruption to the supply. If a fault were to develop in an unprotected component of a supply system, the sustained feeding of power into it would probably lead to a serious breakdown and fire, with the risk of a long-maintained interruption of the supply. Occurrences of this nature have taken place during the last few years due, for example, to leakages from transient faults on overhead lines and leakages due to fires resulting from sustained arcing on unprotected apparatus. These risks are uneconomic and should be guarded against by safeguards of the type described in this paper, adequate to protect the network from damage.

New Museum of the University of Colorado

PROF. T. D. A. Cockerell writes: "When I came to the University of Colorado in 1904, there was no museum. Judge Junius Henderson, a lawyer, but also a very keen amateur naturalist, became honorary curator of the then insignificant collections. Owing to his energy and enthusiasm, the collections grew, and in course of time Henderson was made professor, and giving up his law, devoted his whole time to the Museum. Until recently, the collections were housed in one wing of a building devoted to instruction, and having become very extensive, were crowded so that it was difficult to find room for anything more. The collection of molluscs, in particular, is one of the best in America, and the many fossils include the types of numerous species of insects, shells and plants. The Museum has now moved into a new building, shown herewith. There are fine exhibition galleries for the zoological specimens, for the fossils and minerals, and for the important collections gathered by Earl Morris, representing the work of the ancient inhabitants of south-western North America. It is greatly regretted that Junius Henderson died on November 4, after a very long illness, and was not able to see the fruition of his years of labour in the new building. He has been succeeded by Prof. Hugo Rodeck."



MUSEUM OF UNIVERSITY OF COLORADO

Archæological Discovery at Sakkara, Egypt

THE discovery at North Sakkara, forty miles south of Cairo, of a tomb which it is thought may prove to be that of Menes, the first king of the First Dynasty of Egypt (c. 3300 B.C.), is of exceptional interest, both on account of its historical associations, and also in view of the fact that the tomb of this monarch had been thought to have been discovered many years ago by Sir Flinders Petrie at Abydos. The grounds for this tentative attribution of the tomb now found are the hundred or more clay sealings bearing the name 'Aha', generally identified as that of King Menes, and the fact that no other name appears. The discovery was made by Mr. Walter Emery, who has been engaged in excavation on the site for the past three years. Of all the tombs brought to light here up to the present, this is the largest. It contains five chambers. Its roof had fallen in and it had been plundered; but according to the reports in *The Times* of January 7–8, associated with the skeletal remains of two aged individuals was a large number of antiquities, of which the most important are quantities of stone and alabaster jars, many inscribed with the name of the king. The pottery includes shapes not hitherto recorded in Egypt. In addition to slate palettes there are fragments of funerary furniture, among which are the traditional ivory bull's legs of chairs and parts of a wooden bed similar in design to that already known as belonging to Queen Hetepheres of the Fourth Dynasty. A novel feature of the tomb is the coloured reed matting, which was affixed to the clay walls while they were still wet, forming, it is pointed out, a primitive kind of wall-paper. Many of the sealings bear inscriptions in black ink. Mr. Emery proposes to excavate below the adjoining Third Dynasty tombs in the hope that the discovery of the burial places of the king's servants will confirm the tentative attribution of the tomb to Menes.

Recent Acquisitions by the British Museum

IN the announcement of the additions to the archæological and ethnographical collections of the British Museum (Bloomsbury) during the past month it is stated that the antiquities from Skara Brae, Orkney, which were deposited in the collections on loan in 1933 have now been given to the Museum by the owner, Mr. Walter G. Grant. It will be remembered that this site was excavated by Prof. Gordon Childe, whose careful investigation of this remarkable prehistoric town, or village, revealed a picture of early culture so complete as to constitute on its primitive scale something in the nature of a 'Knossos' of the north. Among other antiquities accruing to the Museum are the remarkable and important collections of bronze knives, spear-heads and bracelets, gold ornaments and pottery acquired by Sir Leonard Woolley in his excavations at Atchana in Syria, including pottery imported from Cyprus and Mycenæ, as well as local ware of about 1650–1450 B.C. in imitation of Cretan pottery of Minoan type. The National Art Collections Fund has given a slab from the stone balustrade of a staircase of the palace at Persepolis, dating from the reign of Darius the Great or Xerxes, somewhere between 520 and 460 B.C. It is carved in relief with the figure of a human-headed lion, winged and wearing a horned headdress. The Christy Trustees have presented a fine and important group of Peruvian pottery from the southern coastal area of Peru in the neighbourhood of Nasca. This Nasca ware, now thought to date from about 200 B.C. to A.D. 200 is an early, though not the earliest, form of Peruvian prehistoric pottery, and is distinguished by the variety of colouring and the fineness of line of its painted decoration.

Television Receivers

IN the General Electric Co.'s (G.E.C.) *Journal* of May and August a description is given by D. C. Espley and G. W. Edwards of television receivers made by the G.E.C. and how they have withstood the tests to which they have been subjected. Since the Commission, formed in May 1934, considered the position of television as a public service, it has come very much to the front. The Commission decided that the standard picture should not be less than 240 lines, with 25 frames per second as the repetition frequency. They further recommended that work should be started on an experimental transmitting station with a 450 line 50 frame per second. The G.E.C. Research Laboratories concentrated, therefore, on the forthcoming transmissions from the Alexandra Palace. It was originally expected that this transmitter would provide good signals within a circular area of 25 miles radius. Results with the receivers have exceeded expectations. At Reading (39 miles), Tunbridge Wells (38 miles), Maidstone (38 miles), Farnham (42 miles) and Brighton (56 miles) the results are entirely satisfactory. Using a modified set, it was found possible to obtain a well-synchronized picture at the G.E.C. Radio Works at Coventry (80 miles), although at this distance the appreciable 'background' noise must produce visible effects on the picture. Apart from the effects of local irregularities, it is now stated that the field strength round the transmitter has an almost circular distribution. The small irregularities are generally due to shadows produced by the proximity of buildings and the contour of the hills. In a few cases it was found necessary to erect aerials with directional properties either for raising low field strength or to avoid local interference when it is excessive.

Agricultural Advice

THE Harper Adams Agricultural College, Newport, Shropshire, has issued a review of its advisory work in the West Midland province during 1936–37 (Adv. Rept. No. 12, pp. 23, May 1937). This is contributed by the advisory staff of the College, and bears the title of "Harper Adams Adviser". Topics of special interest are described, and the most significant tendencies are shown, but no attempt is made to condense the whole advisory activity into this small volume. Mr. F. S. Dennis shows, among other things, the high cost of milk production in Warwickshire, and indicates the lines of heavy expenditure. The correction of heart-rot in sugar beet, and 'Raan' in swedes, by the application of borax, is one interesting feature of Mr. W. Morley Davies's contribution, and the yield of milk deficient in butter-fat and total solids during spring and early summer also receives attention. This is a question vital to dairy farmers, for many cows do not provide milk which reaches the necessary legal standards at this period. "Some Causes of Winter Wheat Failure" is the main topic of Mr. H. C. F. Newton, the advisory entomologist, whilst Mr. N. C. Preston discusses the fungus disease of the same crop, known by the laconic name 'take-all'. Dr. A. Lloyd Provan compares the simple methylene blue test for the number of bacteria in milk, with the more accurate, but cumbersome, plating method. Veterinary investigational work is described by Mr. K. D. Downham.

Australian Science Abstracts

THE Australian National Research Council performs a useful service to its territorial men of science, and to a larger body of workers, by the publication of *Australian Science Abstracts*. This appears quarterly. (Subscription 4*s*. per annum, post paid, from the Editor-in-Chief, Australian Museum, College Street, Sydney.) Sections are devoted to agriculture, anthropology, botany and forestry, chemistry, economics and statistics, engineering, geography, geology, physics, physiology, veterinary science, and zoology. Papers on research findings or communications of general scientific significance are cited, and a short abstract follows most of the titles. Mr. T. Hodge-Smith is the editor-in-chief, and has the assistance of ten honorary abstractors. It is often difficult for the worker in Great Britain to follow research at the Antipodes, but this publication should make such contact possible.

The Reinmuth Earth-grazing Planet, 1937 UB

THIS object was discovered by Herr K. Reinmuth at Königstuhl on Oct. 28^d 22^h $27{\cdot}6^m$ U.T., near o Piscium. Its magnitude was estimated to be 10, but 24 hours later the magnitude was 8, an indication of rapid approach to the earth. As it moved nearly one hour in R.A. in this time, it was obviously fairly close to the earth. Herr Schewick at Sonneberg found images of it on four plates, from October 26 to 29, and orbits were computed from the results. Unfortunately, the short interval rendered the determination of the period very uncertain, and this was found to range between 1·1 and about 4 years. The other elements were computed with as close agreement as could be expected from the data, and the various orbits indicated a small inclination to the plane of the ecliptic—about 6°. On October 31 it made its closest approach to the earth, passing within 400,000 miles—the nearest approach of any minor planet. It reached perihelion about the middle of December, its distance from the sun being then 0·6 unit, that is, 56,000,000 miles. At present it is nearly 1 unit from the sun and about 1·5 units from the earth.

IT is certain that no accurate determination of the time of revolution around the sun is possible from observations over four days, and it is very improbable that it will be seen at the next return, unless by a most fortunate coincidence. Dr. M. Davidson described his computation of the orbit of 1932 HA at the Royal Astronomical Society in May 1932, and predicted that other planets of a similar character, making close approaches to the earth, would be discovered. Since May 15, 1932, when this planet approached the earth within 7 million miles, Adonis came within 1½ million miles in 1936, and now 1937 UB has made a closer approach than either. It is fairly safe to infer that there is a family of these small bodies, their diameter not exceeding 1–2 miles, the orbits of which lie well within the orbit of the earth, and that more of them will be discovered. Probably in the past the earth encountered many of them, but the craters formed, assuming that some of them struck the ground, not the ocean, have been obliterated in the vicissitudes of geological ages. It may be conjectured that our planet has swept up all that could possibly encounter it, for which reason a collision with one of these small bodies is an extremely remote possibility. It is hoped that some light will be thrown on problems of cosmogony through the study of these small planets.

The Night Sky in January

THE planets visible in the south-west sky in the evening are Mars and Saturn, and the approach of the former towards the latter will be noted, until, by February 2, Mars will have passed eastwards of Saturn. On January 20, Mercury is at greatest elongation (24° west) and may possibly be seen about 5° above the south-east horizon on that date at 7^h. In the middle of the month, Sirius souths at 23^h and is one of a conspicuous array of first magnitude stars to be seen southwards near the meridian. In order of apparent magnitude these stars are Sirius ($-1{\cdot}6^m$), Capella ($0{\cdot}2^m$), Rigel ($0{\cdot}3^m$), Procyon ($0{\cdot}5^m$), Betelgeuse ($0{\cdot}9^m$, variable), Aldebaran ($1{\cdot}1^m$) and Pollux ($1{\cdot}2^m$). Two of these stars offer extreme examples of stellar densities. There is Betelgeuse, a super-giant star with a diameter of about 250 million miles, the average density of which is one-millionth that of water. In contrast, the companion of Procyon, an extremely dense white-dwarf star of planetary dimensions, has a mean density more than a million times that of water.

Announcements

PROF. NIELS BOHR, professor of physics in the University of Copenhagen, and Prof. Georges Denigès, formerly professor of biological chemistry in the University of Bordeaux, have been elected *Correspondants* of the Sections of General Physics and Chemistry, respectively, of the Paris Academy of Sciences.

THE honorary membership of the Royal Asiatic Society has been conferred upon Prof. René Dussaud, Secrétaire perpetuel de l'Académie des Inscriptions et Belles Lettres et Conservateur honoraire des Musées Nationaux, Paris, in recognition of his eminent services to Semitic archæology, history and epigraphy.

COLONEL W. B. PURDON, professor of hygiene at the Royal Army Medical College, is to be promoted Major-General and will take over the office of commandant and director of studies at the College in March. He will succeed Major-General W. P. MacArthur, who will assume the appointment of director-general of the Army Medical Service on that date. The new professor of hygiene will be Lieut.-Colonel D. I. Richardson, at present assistant director of hygiene, the War Office.

THE University of Basle has conferred honorary doctorates on Profs. Paul Karrer and Leopold Ruzicka, who hold the chairs of chemistry at the University and Polyclinic at Zurich respectively. The former has investigated the structure of vitamins A and B, and the latter the structure of the sterols including vitamin D and the sex hormones.

THE following appointments and promotions in the Colonial Service have recently been made: Colonial Forest Service: A. R. Barrie (Malaya), J. S. P. Beard (Trinidad), H. A. Douglas (Gold Coast), D. C. Duff (Gold Coast), E. S. Erskine (Malaya), D. B. Fanshawe (British Guiana), F. P. Graves (Malaya), J. H. Nelson Smith (British Guiana); E. Davies, inspector of produce, Nigeria; R. F. Innes, assistant agricultural chemist, Jamaica; B. C. King, chemist and petrologist, Uganda; D. Sturdy (agricultural officer), senior agricultural officer, Tanganyika; Capt. W. S. Aitken, senior veterinary officer, Uganda; Dr. J. Carmichael, senior veterinary research officer, Uganda; R. J. Simmons, senior veterinary officer, Uganda; J. R. V. Smyth, senior agricultural superintendent, Agricultural Chemists' Branch, Jamaica.

A LIST of whole-time awards for scientific research, other than professorships, offered by public and private bodies in Great Britain and Northern Ireland has recently been issued by the Royal Commission for the Exhibition of 1851 (1 Lowther Gardens, Exhibition Road, London, S.W.7. Price 1*s*.). The list comprises fellowships, studentships, scholarships, etc., classified into: (*A*) open awards offered by private and public bodies other than universities or colleges; (*B*) open awards offered by universities or colleges; (*C*) awards restricted to candidates from particular localities or institutions. Particulars concerning each award are given. The list contains much valuable information, and should be kept at hand by heads of research departments and institutions.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

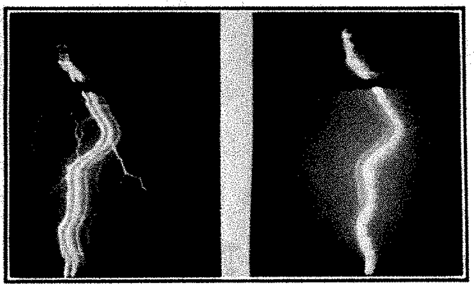
NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 123.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Photography of Lightning in Daytime

THE photographic method of studying the luminous processes in the lightning discharge requires the shutter of a Boys or similar camera to be open before the flash occurs, and hence has hitherto been used only at night. Since the majority of land thunderstorms occur by day, I have for some years been trying various methods of recording lightning in the presence of daylight.

A photo-electric cell backed by a large silvered mirror gives successful results on flashes more than twenty miles away, the steady daylight component being cut out by a resistance-capacity coupled amplifier. Its records are, however, not as useful as photographs.



A chlorine-bromine filter in front of a quartz-fluorite lens can give actual photographs of the discharge without much fogging in daylight, since daylight does not contain the wave-length below 2900 A. which it transmits. The discharge is, however, only weakly luminous on these short wave-lengths, and the range of the camera is not more than three miles.

A very much better device has now been developed in which the discharge takes its own photograph, opening the shutter of the camera before the first main or return stroke occurs. The triggering of the shutter is accomplished by the aid of the train of electromagnetic pulsations sent out by the stepped leader which initiates the discharge. These are picked up by an aerial circuit tuned to the range of frequencies which these steps produce (30–10 k.c./sec.), and after rectification and amplification they operate a thyratron which discharges through a relay, the armature of which pulls on the trigger of a Compur shutter. The lag in the system is less than 0·005 sec.—considerably less than the time taken by the majority of stepped leaders to reach the ground—so that the shutter is open before the first return stroke occurs. The closing of the shutter is effected after 0·5 sec. in the usual way.

The accompanying figure shows two strokes which made up a single flash at a distance of about 2 km., and which were recorded by this device two hours before sunset on a camera with a fixed lens and a moving film. The dart leader to the second stroke is visible to the left of its main portion.

The motion of the film aids considerably in reducing the background fogging due to daylight. The camera can be exposed, for half a second, ten or more times before this fogging becomes serious. This is of importance, since the arrangement is sometimes triggered by discharges within the cloud which involve stepped processes.

The instrument has a range of 15 miles. Its first form was made in December 1936, but much better results have followed the development of a more satisfactory relay device which has been constructed for me by Messrs British Electricon Ltd.

Lightning Strokes

MANY years ago I published a discussion of the origins of lightning discharges[1] which affirmed that a discharge would be expected to begin at a place of maximum electric force (not potential) and to bore its way through the atmosphere, without tearing it, initially along the direction of the force. I now add to this a theorem, due, I think, to Clerk Maxwell, that in an electrostatic field the force cannot be maximum anywhere in free space. It follows that discharges must be initiated, most probably at any rate, within the thunder-cloud. If the discharge begins from a conducting surface, similar reasoning would assign its origin to the more convex parts. As the moving camera of Sir Charles Boys has proved its efficiency in various hands in tracing the course of discharges, this theoretical conclusion may be useful in discussion of observations.

As regards the formation of a thunder-cloud by the separation of the positive and negative ions along opposite directions, the discussions in Prof. Townsend's school on the time required to clear a gas of ions by means of an electric field are relevant.

Doppler Effect of Nuclear Resonance Level

EXPERIMENTAL and theoretical work has shown the existence of remarkably narrow resonance levels for the absorption of slow neutrons in certain nuclei[1-5]. In the cases of rhodium, silver (group A) and gold, the natural half-value width can be estimated as 0·06 volt, 0·05 volt and 0·12 volt, respectively. These values, however, may include errors of the order of 100 per cent. It has been pointed out by Frisch[5] that these widths are comparable with the Doppler width which such resonance must show in consequence of the thermal agitation of the capturing nuclei. According to Bethe and Placzek[3], the Doppler width is

$$\Delta = 4\sqrt{\frac{kT\ .\ E^r}{M}},$$

E_r being the resonance energy and M the mass of the nucleus. This leads to the following widths at room temperature: 0·07 volt for rhodium, 0·1 volt for silver, 0·12 volt for gold. In the case of silver, the Doppler width seems to be even greater than the natural width. In this case, heating a silver absorber should influence considerably the absorption in the middle of the resonance line. In consequence of the Doppler broadening, the absorption in the middle of the line should decrease with increasing temperature of the absorber. Therefore this effect should be observed with a thin detector, which is sensitive principally to the middle of the line.

We tried to find evidence of this effect in the following way. Between a thin silver detector (0·01 mm.) and a source of slow neutrons (400–700 mC. radon plus beryllium surrounded by water), a silver absorber (0·02 mm.) was stretched. This silver foil absorbed 25 per cent of the resonance neutrons of group A detected by the absorber, the activity of which was measured for 45 seconds after an irradiation of 60 seconds. A cadmium filter (1 mm.) was placed between absorber and detector during all measurements. By passing a current of about 200 amperes through it, the absorber could be heated to about 800°. The foil was always well stretched; the detector was cooled by an air current and the water of the source was kept flowing in order to prevent heating. Counting more than 25,000 kicks, the absorber being hot and cold in turns, we found an increase in intensity of $(5{\cdot}2 \pm 1{\cdot}4)$ per cent when the absorber was heated. Not more than 1 per cent increase can be attributed to thermal extension of the absorber. It can be said, therefore, that a change of intensity of more than 4 per cent, or a change of the absorption coefficient of 25 per cent, must be attributed to the Doppler effect. For a thicker absorber (0·1 mm.) no effect was observed. This might have been expected because radiation transmitted by such an absorber is principally concentrated on the borders of the line where the absorption is but slightly modified.

The observed effect provides a possibility of estimating the breadth of the silver resonance line by a direct experimental method.

Thomson Effect of Supraconductive Lead

VARIOUS investigations have proved that the thermo-electric force between supraconductors is zero[1]. This might suggest that the Thomson effect in a supraconductive metal is also zero, although it is conceivable that the Thomson coefficients of different supraconductors have the same but finite value. It was therefore decided to determine the Thomson coefficient of supraconductive lead directly.

The experimental arrangement consisted of a ring of lead wire, to which two copper vessels containing liquid helium were attached at the opposite ends of a diameter. On one side of the ring half way between the containers the bulb of a gas thermometer was attached. The whole arrangement was suspended in a vacuum, and a temperature gradient in the ring was kept up by allowing the helium in the containers to boil under different pressures. Persistent currents in opposite directions were successively set up in the ring, and the gas thermometer read in each case. No change in the temperature of the thermometer could be observed, which means that the Thomson coefficient of the metal is zero, or at least smaller than 4×10^{-10} volts per degree.

This result is interesting in connexion with the specific heat of the supraconducting electrons. The existence of such a specific heat is apparent from the heat capacities of supraconducting metals determined in Leyden[2], and we have evaluated the specific heat of a system of supraconductive electrons by direct determination of the difference in free energy between the supraconductive and the normal state[3]. The fact that this specific heat is not zero means that there is an exchange of thermal energy between the supraconductive electrons and the lattice. Although the theory of the free electrons in metals as yet gives no satisfactory results for the Thomson coefficient (except for the alkali metals), it is evident that the Thomson coefficient is to some extent a measure of the specific heat of the electrons[4]. The fact that in one case the specific heat can be observed directly and in the other case it is not apparent in the Thomson coefficient seems to suggest that, in general, electrons in a supraconductive metal exchange thermal energy with the lattice, whereas those taking part in a persistent current do not.

A more detailed discussion of the result in connexion with the other phenomena of supraconductivity will be given elsewhere.

Nature of the Nuclear Field

AN attempt to explain neutron-proton interaction made by Yukawa[1] in 1935 has been brought to general notice[2,3] in connexion with the new experimental evidence for the existence of a 'heavy electron'[4,5,6].

Although it is premature to draw definite theoretical conclusions from the present experimental knowledge, it is certainly suggestive that a Yukawa particle with a mass of the observed order of magnitude (100 m_{el}) does indeed give nuclear forces of the correct range. As nothing is otherwise known about the strength of the interaction of these particles with protons and neutrons, one can also assume it to be so large as to account for the known magnitude of the neutron-proton force.

Unfortunately, a theory based on the scalar relativistic Schrodinger equation, as suggested by Yukawa, cannot explain the experimentally known position of the ^1S level of the deuteron relative to its ^3S ground state.

It has, however, been found that a more satisfactory result can be obtained if one admits a *vector* wave function for the new particle, such as was used by Proca[7] in a different connexion. Proca's equations can be quantized on lines completely analogous to the Pauli-Weisskopf method[8] for the scalar wave equation, and the resulting neutron-proton potential can easily be determined. Using the most general combination of possible interactions of the Yukawa and Proca type, the potential is found to be

$$V(r) = \left\{ A + B(\sigma_N \sigma_P) + C\,k^{-2}(\sigma_N \text{grad})(\sigma_P \text{grad}) \right\} \frac{e^{-kr}}{r},$$

where k is $2\pi c/h$ times the rest mass of the new particle, σ_N and σ_P the spin operators of neutron and proton respectively and r the distance between these particles. A, B and C are constants and are independent with regard to both sign and absolute magnitude. Therefore an interaction can obviously be chosen which gives the correct triplet-singlet separation.

The nuclear potential now considered most adequate for practical calculations[9] has exactly the spin dependence one obtains from the above expression by putting $C=0$, $A:B=3:5$. It further includes the 'isotopic spin' factor ($\tau_N \tau_P$) which can be accounted for in the field theory here proposed exactly on the same lines as in the case of the Fermi field[10], that is, by assuming that the new particle also has a charged and an uncharged state. It is a question yet to be considered whether a complete description of experimental data may also be possible *without* assuming this uncharged state to exist; also whether any specialized type of interaction of greater simplicity than the above general linear combination might perhaps suffice to fit the facts.

In any case, it is possible to give a field theory in which magnitude and range of the nuclear forces, as well as their dependence on spin and charge, are all accounted for equally well. It appears satisfactory to have such a model, even though its relation to experiment is admittedly quite uncertain.

The details of the calculation will be published elsewhere.

Nuclear Forces, Heavy Electrons and the β-Decay

WE have generalized a theory put forward by Yukawa[1] showing that nuclear forces can be explained by assuming the existence of new particles of mass about two hundred times that of the electron. Our theory is relativistically invariant, and in its present form gives results which we believe are of actual significance for cosmic ray and nuclear phenomena.

Our theory is based on the idea that the proton and neutron are two states of the same particle characterized by the eigenvalues -1 and $+1$ respectively of some operator, τ say, and that transitions may occur from one state to the other with the emission or absorption of a particle of positive charge e and mass M_u. It follows from this that such a particle, which we shall call a U-particle, obeys Bose statistics. In order to explain the β-decay, we must then assume that in certain circumstances an electron may absorb a U-particle by becoming a neutrino or vice versa. Of course, the emission or absorption of a U-particle only takes place observably when it is consistent with the conservation of energy. In other cases the emission or absorption is merely virtual, as an intermediate state, as is the case in the quantum theory of radiation.

The motion of the U-particles is described by a 4-vector U_μ. Denoting by Ψ the wave function for the proton-neutron, which in consequence has two components corresponding to the two states of this particle (each component itself being really composed of the four components belonging to a wave function for a particle obeying the Dirac equation), by ψ the similar wave function for the electron-neutrino, and by φ_μ the electromagnetic potentials, we can derive the complete equations of motion of the whole system in the usual way by the variation of a relativistically invariant Lagrange function with respect to Ψ, ψ, U and φ. Using the methods of the second quantization, the equations can then be written in the Hamilton form necessary for quantum mechanics. Writing

$$G_{kl} = \left(\frac{\partial}{\partial x_k} - \frac{ie}{hc}\varphi_k\right) U_l - \left(\frac{\partial}{\partial x^l} - \frac{ie}{hc}\varphi_l\right) U_k, \quad (1)$$

the equations of motion for the U-particles are

$$h^2c^2\left(\frac{\partial}{c\partial t} + \frac{ie}{hc}\varphi_o\right)G_{ok} + h^2c^2\left(\frac{\partial}{\partial x_l} - \frac{ie}{hc}\varphi_l\right)G_{lk} -$$
$$M_u^2c^4U_k - g\,\overline{\Psi}\,\alpha^k\tau_{NP}\,\Psi - g'\,\psi\,\alpha^k\,\tau_{en}\,\psi = 0, \quad (2)$$

and

$$G_{ok} = -\left(\frac{\partial}{c\partial t} + \frac{ie}{hc}\varphi_o\right) U_k - \left(\frac{\partial}{\partial x_k} - \frac{ie}{hc}\varphi_k\right) U_o, \quad (3)$$

and their conjugate complex equations. $l, k = 1, 2, 3$ and g, g' represent the interaction of the U-particles with the proton-neutron and electron-neutrino respectively, and are the only two arbitrary constants in our theory. τ_{NP} is a matrix representing the change of a proton into a neutron and τ_{en} similarly represents the change of a neutrino into an electron. In addition, exactly as in electrodynamics, the equation

$$h^2c^2\left(\frac{\partial}{\partial x_k} - \frac{ie}{hc}\varphi_k\right)G_{ok} + M_u^2c^4U_o + g\overline{\Psi}\tau_{NP}\Psi$$
$$+ g'\overline{\psi}\tau_{en}\psi = 0, \quad (4)$$

has to be imposed as a boundary condition. The equation of the proton-neutron is

$$\Big[c\,\alpha_\mu\Big(p_\mu - \frac{e}{c}\varphi_\mu\tau_p\Big) + \beta\Big(M_N c^2\tau_N + M_P c^2\tau_P\Big) + g\,\Big(U_\mu\alpha_\mu\tau_{PN} + \overline{U}_\mu\mu_\mu\tau_{NP}\Big)\Big]\,\Psi = 0, \quad (5)$$

where τ_P and τ_N are matrices which are unity only when the particle is a proton or neutron respectively, and zero otherwise. M_N and M_P are the masses of the neutron and proton. A similar equation holds for the electron-neutrino. The charge density of the U-particles is given by

$$\sigma_0 = iehc\,(\overline{U_k}\,G_{ok} - U_k\,\overline{G_{ok}}), \quad (6)$$

and the commutation rules being

$$-\,ihc\,(\overline{G}_{ok}\,(x^1)\,U_l\,(x) - U_l(x)\;\overline{G}_{ok}\,(x^1)\,) = \delta_{kl}\,\delta\,(x-x^1) \quad (7)$$

and the conjugate equations, the existence of U-particles of positive and negative charge follows automatically as in the case of the Klein-Gordon equation treated by Pauli and Weisskopf[2].

The purpose of this note is to point out the following consequences of the theory.

(1) A positive U-particle at rest may disintegrate spontaneously into a positive electron and a neutrino. This disintegration being spontaneous, the U-particle may be described as a 'clock', and hence it follows merely from considerations of relativity that the time of disintegration is longer when the particle is in motion. We believe that this may have to do with the fact observed by Blackett and others that below 2×10^8 e.v. most cosmic ray particles are electrons, above this energy heavy electrons. In a previous paper[3] we have shown that the experimental evidence requires that heavy electrons can apparently turn into ordinary electrons. Our U-particles are then to be identified with the heavy electrons, and it follows that most of the heavy electrons have been created either in the earth's atmosphere or not very far from it.

(2) The U-particles will suffer large energy losses in addition to the ionization and the *Bremsstrahlung*, due to collision with neutrons in which they are absorbed and re-emitted with less energy (analogue of the Compton effect).

(3) On colliding with a neutron they may be absorbed to form a fast proton, but only in the presence of other particles.

(4) It gives a relativistic interaction between a proton and a neutron which in the non-relativistic case reduces to the Heisenberg-Majorana exchange force of the type $-g^2e^{-M_u cr/\hbar}/r$.

(5) It may be objected that the use of the Dirac equation to describe the proton-neutron is incorrect inasmuch as it gives a wrong value for the magnetic moment. This objection, however, fails if the magnetic moments of the proton and neutron can arise through their interaction with the U-particles. It is quite easy to see without any calculation that our theory gives magnetic moments of opposite sign to the proton and neutron, as is required by experiment.

(6) When the maximum energy of the β-ray spectrum is not too large, it can be shown that our theory reduces exactly to Fermi's. In the general case, however, characteristic differences will appear which may improve the agreement with experiment.

Lastly, we would remark that the U-particles being charged, they cannot explain the close-range proton-proton interaction. To formulate this, we would have to introduce a neutral particle N of about the same mass M_u, which obeys similar equations to those for the U-particles and can be absorbed and emitted when a proton jumps from one energy state to another. The introduction of such a particle may not seem very arbitrary when we consider that it would give us a symmetrical state of affairs, with all the particles falling into three groups with masses of the order $M_P \simeq 1840\ m_e$, $M_u \approx 200\ m_e$, and m_e, there being positive, negative and neutral particles of each group. The introduction of the N-particles would give, in addition to the processes mentioned above:

(7) The absorption of a positive U-particle by a neutron and the re-emission of an N-particle, and vice versa. This would give rise to a type of chain U–N–U, etc., such as we have already discussed[4] in connexion with the proton-neutron interaction.[5]

The detailed calculations are being published elsewhere.

Sulphur Content of the Intercellular Phase of the Wool Fibre

RECENT advances in the chemistry of wool and wool textile processes have been based on the simple view that the fibre consists of peptide chains bridged by cystine and salt linkages. The differences between the constituent phases of the fibre and its cells were reserved for investigation until the significance of main structural features had been determined. In connexion with a detailed study of the reactivity of the sulphur linkage in animal fibres[1], however, we have found it necessary to determine whether the intercellular phase of the fibre differs in sulphur content from the cortical and cuticular cells.

The investigation was in progress[2] when Stakheyewa-Kaverznewa and Gavrilow[3] reported that the cells isolated from wool by means of pancreatin possessed a sulphur content of 3·05 per cent compared with 2·91 per cent for the original wool. This result suggested that the intercellular phase was deficient in sulphur, in agreement with Astbury and Woods' hypothesis[4], but some doubt remained because Stakheyewa-Kaverznewa and Gavrilow did not restrict their attention to non-medullated fibres, and took no account of the action of light in reducing the sulphur content of the tips of the fibres. Preferential isolation of intact cortical cells from fibres which have been damaged by exposure to light and contain sulphur-free medulla, would give the observed result whether or not the intercellular phase is deficient in sulphur.

We have, however, been able to show that Stakheyewa-Kaverznewa and Gavrilow's conclusion is correct, although when intact non-medullated fibres are used, the difference in sulphur content between the fibres and their constituent cells is higher than they report. The root ends of non-medullated, Australian 64's merino wool staples were used for the investigation. After purification by extraction with alcohol, ether and water, the wool was retted at 35° C. in 1 per cent trypsin solution at pH 8·6[5]. Although the fibres retained their original form at the end of fourteen days, they crumbled readily when rubbed with water on a glass plate. The cells isolated in this way were washed repeatedly by decantation until the wash-water had a pH of 6·9 and gave only a faint ninhydrin reaction after concentration. Part of the material so obtained was retained for sulphur determinations, and the remainder treated with fresh trypsin solution for a further sixteen days. At the end of this time, the cells were again washed, separated and dried. The sulphur contents of the various materials, dried to constant weight *in vacuo* over phosphorus pentoxide, were determined by the Carius method and are given below.

Material	Time of retting (days)	Sulphur content (per cent)	Ash content (per cent)
Original wool .	—	3 52 3 50	0 63
Cells	14	3 61	0 26
Cells (treated with HCl to reduce ash content)	14	3 65 3 65	0 16
Cells . .	30	3·87 3 86	—

From these results, it seems clear that the amorphous intercellular phase of the fibre has a smaller sulphur content than the cells. The sharp rise in sulphur content of the latter, after the second treatment with trypsin, is probably due to more complete removal of the amorphous phase from the separated cells, but the possibility of attack on the cells, with isolation of more crystalline components, is under examination.

Vitamin C and Phosphatases

THE influence of vitamin C on enzymes offers a new approach to the mode of action of the vitamin in plant and animal life. The presence of vitamin C in green leaves and storage organs of plants in which the synthesis and cleavage of organic phosphorus compounds play an outstanding part has suggested the investigation of a possible biochemical relationship between the vitamin and phosphatases. The present note relates to a study of the influence of vitamin C, either alone or in presence of other substances of physiological importance, on the enzymic splitting of phosphorus compounds by highly active preparations of phosphatase prepared from sprouted soybean as described by me[1].

It was found that the oxidation of vitamin C by metallic catalysts like $Cu^{\cdot\cdot}$ and other oxidizing agents brings about the inhibition of the activity of the phosphatase. The inhibition by the vitamin C-copper complex was annulled by glutathione, cysteine, cystine, hydrogen sulphide and reducing agents like potassium cyanide and sodium hydrosulphite. Oxidizing agents like potassium ferricyanide in presence of vitamin C inhibit the activity of the enzyme. The rate of oxidation of the vitamin appears to control the degree of inhibition. Substances which prevent the oxidation of vitamin C or decrease its rate of oxidation prevent inhibition or decrease the extent of inhibition of the activity of the phosphatase.

The hydrolysis of pyrophosphate was less affected by the vitamin C-copper complex than that of glycerophosphate. This difference in behaviour of pyrophosphate is found to be due to its stabilizing action on the vitamin against catalytic oxidation[2]. The results, therefore, suggest that pyrophosphate may have a physiological function in protecting the vitamin against oxidation, thereby regulating the activity of the phosphatase. Dehydroascorbic acid either alone or in presence of $Cu^{\cdot\cdot}$ was found to have no influence on the activity of the phosphatase.

Hence it may be stated that the regulation of phosphorus metabolism in plants, by the interaction of phosphatases, vitamin C and glutathione, in the sense of hydrolysis on one hand and synthesis on the other, possesses a physiological significance. The opposite actions of vitamin C and glutathione suggest, therefore, a possible means by which the action of phosphatases may be controlled in plant life.

It is hoped to extend these studies to animal phosphatases and to determine the relation between glutathione, vitamin C and phosphatolysis. Full details of the work will be published elsewhere.

Formation of Radio-Phospholipid by Isolated Tissues of the Rat

IN a forthcoming paper[1] will be published the results of a study of phospholipid formation in the living rat by means of radioactive phosphorus. The content of labelled phospholipid sampled at various intervals suggested that certain tissues of this animal, namely, the liver, intestine and possibly kidney, engaged in synthesis. Similar observations have been reported by Artom *et al.*[2]. The possibility, however, that one tissue carried on this synthesis while other tissues concentrated phospholipids could could not be ruled out. Warburg's method for the study of the metabolism of surviving tissues suggested a direct attack on the relative roles of the various tissues of the body in phospholipid formation. The experiments described below were performed to test the possibility of this synthesis by tissues surviving after excision from the body.

The tissues, as sections or slices, were treated after the manner of Krebs[3] with the modified phosphate buffer in the presence of oxygen. Both phosphate solutions contained radioactive phosphorus. Phospholipid was extracted from the tissues and substrate by means of alcohol and ether. The petroleum ether extract of the alcohol-ether soluble fraction was shaken vigorously for three hours, with an aqueous solution of inactive sodium phosphate, to remove water-soluble phosphorus compounds. This procedure was repeated twice. The absence of radioactivity in the last aqueous extract indicated that the removal of the contaminants was complete. The phospholipid of the petroleum ether extract was then precipitated in the usual manner and its radioactivity determined by means of a small Geiger counter. Egg lecithin was added to the petroleum ether solution to serve as a carrier for the labelled phospholipid.

For controls, tissues killed either by hot alcohol or by boiling for several minutes in Krebs solution, were treated in the same manner as the surviving tissues. The values for the controls were zero within experimental error.

The formation of labelled phospholipid by surviving liver, intestine and kidney is recorded in the accompanying table. The results show that phospholipid formation is not confined to one tissue. The high activity of the kidney is of particular interest in this regard. The synthesis effected *in vitro* by these tissues is comparable with that found in the same tissues of the intact animal[1]. The results suggest that glucose stimulates phospholipid formation, but further work on this point as well as other tissues involved in synthesis is in progress. It should be noted here that the term formation or synthesis does not permit differentiation between the various ways in which phosphorus may become incorporated into the phospholipid molecule. The possibility of interchange has not been ruled out[4].

Tissue	Experimental period	Per cent labelled phosphorus as phospholipid (per gm. dry defatted tissue)	
		No glucose	Glucose
	hours		
Liver	2	0·52 (single result)	0·65 (single result)
	3	0·83 (average of 2 results)	1·80 (single result)
	4	1·31 (single result)	
Intestine	0·75	0·12 (single result)	
	1·25	0·19 (single result)	
	1·5	0·24 (single result)	
	2	0·34 (average of 2 results)	1·24 (single result)
	3	0·38 (single result)	0·55 (single result)
Kidney	1	0·58 (average of 2 results)	
	2	1·25 (single result)	
	3	1·79 (average of 3 results)	

The detection of the minute quantities of phospholipid (so low as 10^{-4} gm. of phosphorus were studied) synthesized by the tissue slices was made feasible by the use of a sensitive indicator such as radioactive phosphorus. Our thanks are therefore due to Prof. E. O. Lawrence and the members of the Radiation Laboratory for the preparation of the radioactive phosphorus used in this study.

Mode of Dissemination of Potato Virus X

VIRUS X is the commonest and most ubiquitous of all the potato viruses, but every attempt to discover an insect vector or other natural method of spread has failed. It has now been found, as a result of three experiments carried out in 1937, that it spreads freely from potato plant to potato plant under controlled experimental conditions by leaf contact, especially that brought about by air currents, without the intervention of instruments or human agency, and in circumstances excluding insect participation.

In the first experiment, four lots of X-free tuber portions (derived from 14 quartered tubers, and 13 halved ones in addition in (*A*) and (*B*) below) were interplanted under different conditions with X-infected tubers. The first lot of 27 pieces (*A*) was grown in pots on one side of a small insect-proof glass-house compartment with the haulms of the healthy and diseased plants in contact, and 14 of the healthy plants were in the same pot as a diseased plant, and 13 in separate pots. In order to increase leaf contact, an oscillating electric fan was allowed to play on the plants from a distance of 3 ft. for about nine hours per week. The second corresponding lot (*B*) was grown on the opposite side of the same compartment 3 ft. away, under exactly the same conditions in all respects but two: (1) the haulms of the diseased and healthy plants, whether growing in the same or separate pots, were separated by cylinders of ½-inch mesh wire netting surrounding the former; and (2) the fan did not play on them.

The third lot (*C*), consisting of 14 pieces, was planted in three drills in the field with the diseased and healthy plants alternating at a distance of one foot from each other, and three of the healthy tubers and the adjacent diseased ones were planted in 9-inch pots sunk in the ground to minimize root contact. The fourth corresponding lot (*D*) was grown 4 ft. away under the same conditions in all respects except that the haulms of the diseased plants were enclosed in two cylinders of ½-inch wire mesh one inside the other with a space of about 1 inch between. The haulms were isolated in this way so as to maintain the usual spacing and root contact, without making insect access more difficult above or below ground.

The presence of virus X was determined by inoculation to *Datura Stramonium* at intervals. All the plants from healthy tubers proved to be free from virus X at first, but infection afterwards appeared in some, and the following were the final results on *Datura*:

A	House :	haulms in contact (fan)	8/27 infected
B	House :	haulms separated	0/27 ,,
C	Field :	haulms in contact	2/14 ,,
D	Field :	haulms separated	0/14 ,,

Of the eight plants infected in the house, three were in separate pots and five in the same pot as a diseased plant. There was no evidence of infection through root contact either here or in lot *B*.

A further experiment was later carried out in the house on the same general lines to assess the effect of the fan, the plants being in separate pots. All the plants from X-free tubers proved healthy in the first three tests, but they afterwards developed X infection to the following extents:

House :	haulms in contact (fan)	4/16 infected
House :	haulms in contact	1/16 ,,
House :	haulms separated	0/16 ,,

The fan set up an air current of 6 m.p.h. at a distance of 3 feet, which did not injure the leaves. The results are interpreted as showing that virus X is readily disseminated within a potato crop by leaf contact, probably mainly under the influence of wind. This is in harmony with observation, for the virus is a universal one, which spreads even in the best districts, and demands a universal agency, unlike the aphid-borne viruses, the distribution of which is limited by ecological factors. It is likely that no insects are involved, and the danger of infection underground is slight or absent. The question is not prejudged whether the foliage must be in actual contact or whether any other agent may be able to convey the virus from a greater distance.

Cytology of Spruce Sawfly and its Control in Eastern Canada

In the autumn of 1930, serious defoliation of some 2,000 square miles of spruce forest by a species of sawfly was discovered in the interior of the Gaspé Peninsula, Province of Quebec, Canada. This has now increased to about 8,000 square miles of heavy infestation. The insect, previously unreported in America, was identified as *Diprion polytomum* Hartig, a species known in Europe for more than a hundred years.

The 'typical' European and Canadian forms are very similar in appearance but differ primarily in their type of parthenogenetic reproduction. In the absence of fertilization, eggs of the former develop into males, while those of the latter almost invariably produce females. The rare males (1 in 1,200) are almost always sexually functionless. Further, the Canadian form spins its cocoons in the moss and litter below the tree, and in general the larvæ remain dormant for more than a year, whereas the European form as a rule spins in the lower foliage or herbaceous growth above ground, and the larvæ appear to develop without going into diapause.

As the spruce is by far the most important forest tree in Canada, the suppression of such a destructive insect is clearly of vital importance. That the physiological characters which distinguish it from the European form are of considerable advantage to it is self-evident. Moreover, native parasitic insects are almost non-existent. In an attempt at control, large numbers of European parasites are being introduced. By co-operating with the Farnham House Laboratory, the Belleville Laboratory in Ontario has been able to breed and release during 1937 alone more than 47 million insects capable of attacking the sawfly in the feeding and dormant stages.

If, as entomologists are led to assume, this insect was originally introduced from Europe, the physiological differences are either secondarily acquired or already exist side by side in different European strains. To settle this question the Dominion Entomological Branch has provided facilities and financial aid for a cytogenetic investigation.

The chromosomes have been studied in both sexes of *Diprion polytomum* collected from Eastern Canada and Hradec u Opavy, Czechoslovakia. In the Hradec male and female there are six and twelve chromosomes respectively; in the Canadian form there are seven and fourteen. Despite the difference in the type of parthenogenesis shown by the two, the sex-determination in both is of the haplo-diploid type common in the Hymenoptera.

In males of the two forms no difference was found during spermatogenesis. The chromosomes of the first spermatocytes, during prophase, fail to synapse and the whole complement passes towards the centrosome of the unipolar spindle. At second metaphase each chromosome splits longitudinally and the halves migrate towards the poles of the bipolar spindle. The second spermatocyte cleaves into two equal-sized spermatids possessing the same number of chromosomes as the soma.

In the females the oogonia are diploid. In both forms the oocyte chromosomes pair to form the haploid number of tetrads, and their chiasmata entail an orientation of the chromosomes such as must lead to a reduction in number at the first division of meiosis. It is obvious that, in the Canadian form, the diploid number must be restored by some form of auto-fertilization.

These preliminary results do not eliminate the possibility of the two forms occurring together in Europe, for if they overlap in distribution, and their progeny mix, this would mask the fact that parthenogenesis in one of them leads to the production of females. To test this possibility material was obtained from different bio-climatic regions in Czechoslovakia.

Females from five distinct regions laid unfertilized eggs which developed into 36 larvæ. These all gave small-sized cocoons which were spun up in the foliage, and upon reaching maturity proved to be males; two from different mothers were found to possess the male complement of six chromosomes. On the other hand, a virgin female from another region produced 13 cocoons which were not only large (presumably female) but were buried in the debris on the floor of the rearing-globe. Their chromosome number has not yet been established, for the significant reason that the larvæ have gone into diapause.

Clearly then a form exists in Europe which (at least under laboratory conditions) resembles the Canadian form and differs from the European form hitherto recognized in three of the four essential characters. If, in addition, this new European strain is found to possess the fourth characteristic, the chromosome number fourteen, the probability of introduction from Europe will be considerably strengthened. Such a count has already been obtained in a female from Czechoslovakia, but its type of parthenogenesis was not determined.

A fellowship awarded by the Royal Society of Canada is enabling this work to be continued.

The Zodiacal Light at a Total Solar Eclipse

In connexion with the interesting note[1] from Prof. F. J. M. Stratton concerning the eclipse observations of Mr. Honda at Hokkaido on June 19, 1936, may I point out that S. P. Langley and S. Newcomb apparently observed a similar phenomenon at the eclipse of July 29, 1878. In his description of this eclipse in "The New Astronomy", Langley says: "The most extraordinary thing, however, was a beam of light, inclined at an angle of 45 degrees, about as wide as the sun, and extending to the distance of nearly six diameters on one side and over twelve on the other; on one side alone, that is, to the amazing distance of over ten million miles from its body. Substantially the same observation was made, as it appeared later, by Prof. Simon Newcomb at a lower level. The direction, when more carefully measured, it was interesting to note, coincided closely with that of the Zodiacal Light and a faint central rib added to its resemblance to that body."

At the eclipse of June 8, 1937, I have recorded this phenomenon photographically. From Callan, Peru, a pass in the Cordillera Negra of the Andes at an elevation of 14,000 feet above sea-level, using a Schmidt camera of four inches aperture and of focal ratio $f/1$, three photographs were taken. The first exposure was of 50 sec. duration on a green-sensitive film especially prepared for me by the research laboratory of the Eastman Kodak Co.; the second was 40 sec. on a super-sensitive panchromatic emulsion, and the third 20 sec. on a double-coated orthochromatic emulsion. All these films with the exception of the first show, in addition to the usual coronal streamers, a double-wedge-shaped region along the ecliptic (the points of the wedge meeting at the sun) faintly brighter than the remaining region around the sun. This region extends from the visible horizon to the edge of the film, a distance of about twelve degrees.

The sky was very transparent in the neighbourhood of the eclipsed sun. Streamers of the corona could be seen clearly for three solar diameters from the limb of the sun, with some uncertainty for four diameters. These streamers were recorded photographically only as far as they were observed visually, this despite the fact that 30-sec. exposures on the night sky on similar films recorded stars too faint to be seen by the naked eye.

It may be added that a thorough investigation of the camera employed and of the films used indicates that this is not a photographic fault. The circular disks of film were developed in a round tray, with agitation from all directions. The wedge-shaped areas stop sharply at the clear edge of the film which had been hidden by the film-holder, and at the silhouette of the mountains on the horizon.

I hope to photograph this phenomenon again at the total solar eclipse of October 1, 1940, from near Recife, Brazil.

Molecular Shape and Size of Thymonucleic Acid

A STUDY has been made of the viscosity and the double refraction of flow of thymonucleic acid in water solution. The sodium salt of the acid was prepared according to the method of Hammarsten[1], and by high-pressure filtration cleared of the remaining few particles of denatured protein[2], so that the solution could be studied by optical methods. The hydrodynamic relations between internal friction and particle size of rod-suspensions[3] and the observations on double refraction of flow[4] permit the following conclusions from the data:

(1) The molecules of sodium thymonucleate have in solution the form of thin rods, the length of which is approximately 300 times their width.

(2) The molecular weight of the preparation studied lies between 500,000 and 1,000,000, in agreement with previous indications from filtration experiments[2] and from preliminary studies in the ultra-centrifuge, made by The Svedberg, that the molecular weight must be high.

(3) The molecules are optically negative; that is, their great polarizability is perpendicular to the longitudinal axis.

(4) The optical anisotropy is very great. The macromolecule must contain strongly double-refracting components arranged in a definite pattern. Apparently the purine and pyrimidine rings lie in planes perpendicular to the longitudinal axis of the molecule.

These results will, it is hoped, be useful with reference to the chemical analysis of chromosome structure[5,6].

A discussion is deferred for the present.

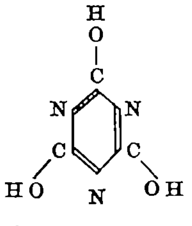
Crystal Structure of Cyanuric Acid

CYANURIC acid crystallizes in pseudo-rhombic prisms. Rotation and Sauter photographs round the three axes show that two projections have real rhombic symmetry whilst the third shows pseudo-symmetry caused by the fact that in this nearly exactly rectangular projection the atoms lie pseudo-symmetrically with respect to the two (at 82°) intersecting diagonals of equal length.

All atoms lie in planes, thus giving the molecule a planar configuration as is to be expected from the structure



The intermolecular forces are, as is shown by a determination of atomic parameters, hydrogen bonds linking together a nitrogen atom from one molecule to an oxygen atom of another molecule.

Full details will be given in the *Zeitschrift fur Kristallographie*.

The Apparent Size of the Sun

THE illusion described by Dr. Vaughan Cornish in NATURE of December 25, 1937 (140, 1082) can be seen if the sun is looked at for an instant and then the observer turns and looks towards the horizon. An after-image will be seen. Carry this up in the sky, and it will be seen to shrink.

Another trick to play with this after-image is to stare at the setting sun; shut your eyes and turn them through about ten or fifteen degrees; open them and turn them slowly and *as regularly as possible* towards the sun and beyond it. The after-image will not be a streak but a row of separate images.

Axial Spin and Weapons of the Ancients

I THINK the answer to Mr. L. J. D. Richardson's query[1], "Does an arrow rotate?", is that some do and some do not.

A toxophilite may assure us that, by the feathering of his arrows, a slow rotary motion is imparted, and, from an examination of some modern examples, it would appear to be a just claim. But there is no evidence that the arrows of the ancients closely resembled the modern types. Many of the flint heads of great antiquity are of such a shape and size that their use would be likely to prevent sustained rotation and, as is well known, the feathers may be tied to, as well as inserted in, the butt-end. Sometimes pieces of leaf or skin were used in place of feathers, so that there was diversity of type as well as crudeness in construction.

In the crude examples, the feathering could serve only as resistance to that portion in rear of the centre of gravity, as Sir Gilbert Walker states, but I should prefer to describe it as a definite aeronautical device whereby any deviation from the true flight path was automatically corrected by reason of the fact that some of the surfaces (there were usually three set at angles of 120° to one another) were presented to the air at an angle and a righting force thus exerted.

Points from Foregoing Letters

A NEW device for obtaining photographs of lightning in daylight is described by Dr. B. F. J. Schonland. The electromagnetic pulsations sent out by the 'leader' stroke which initiates the lightning discharge are picked up by an aerial circuit and used to pull a trigger opening the camera shutter. The lag is less than 0·005 sec., so that the shutter is open before the first return stroke of the lightning occurs.

Drs. H. von Halban and H. Paxton have found evidence of broadening of the absorption line for slow neutrons in silver when the absorber is heated. This effect is identified with the Doppler broadening resulting from the thermal motion of the capturing nuclei.

No change in temperature (Thomson effect) is observed at a given point in a supraconductor in which a temperature gradient exists, when a current is reversed, according to Dr. J. G. Daunt and Dr. K. Mendelssohn. The authors suggest that this, together with the fact that the specific heat is not zero, indicate that, in general, electrons in a supraconductive metal exchange thermal energy with the lattice, whereas those taking part in a persistent current do not.

Dr. N. Kemmer suggests a modification of Yukawa's theory of the nuclear field which, it is claimed, describes completely the known exchange character of nuclear forces as well as their range and magnitude.

On the same subject, Dr. H. J. Bhabha gives equations and describes the properties of 'U-particles' bearing positive charge and having a mass about 200 times that of an electron. The existence of a neutral particle N, of the same mass, is also allowed for, so that nuclear physics would then have three symmetrical groups of particles, each having a neutral, a positive and a negative constituent. The particles of the first group have mass equal to that of an electron, those of the second group being 200 times heavier, and the third group (protons and neutrons) 1,840 times heavier than the electron.

Further evidence that the cortical and cuticular cells in the wool fibre contain more sulphur than the total wool (from which they are obtained by the action of trypsin) is adduced by Dr. J. B. Speakman and Dr. P. R. McMahon. This indicates that the intercellular phase contains less sulphur than the cells.

K. V. Giri reports that in a system containing vitamin C, glycerophosphate and phosphatase, when the vitamin C is oxidized by metallic catalysts like copper ions and other oxidizing agents the activity of the phosphatase is inhibited. Glutathione and other reducing agents remove this inhibition.

A group of workers from the University of California presents results, obtained with radioactive phosphorus as indicator, showing that phospholipids are synthesized by surviving liver, intestine and kidney.

J. B. Loughnane and Dr. Paul Murphy report that they have obtained free transmission of potato virus X by leaf contact, especially under the influence of air currents, and they suggest that this explains the ubiquity of this virus, the distribution of which probably does not depend on biological agents.

Serious effects of infestation of Canadian spruce forests by the sawfly, *Diprion polytomum*, and steps taken for its control, are reported by Dr. S. G. Smith. The Canadian variety of sawfly differs from the European in that the unfertilized eggs give rise to females instead of males. Also the basic chromosome number is seven instead of six. The author suggests that the Canadian variety may exist in small numbers in Europe, whence it may have been introduced into Canada.

From hydrodynamic relations between internal friction and particle size and from observations on double refraction of flow, R. Signer, Prof. T. Caspersson and Prof. E. Hammarsten deduce that the molecules of sodium thymonucleate, a constituent of chromosomes, have, in solution, the form of thin rods, and a molecular weight of between 500,000 and 1,000,000.

Research Items

Vaulted Tombs of Knossos and Ras Shamra

SIR ARTHUR EVANS in *Man* of December reviews the evidence bearing on the dating of the vaulted tombs of Knossos in relation to those of Ras Shamra, Syria. In the second report on the tombs of Knossos (1914), the smaller built tomb at Isopata was assigned to the last Palace Age on account of the Late Minoan II ceramic content and a gold signet ring. The chronological succession of Minoan engraved gems now established counteracts this evidence. A chalcedony bead seal from the covered part of the cist belongs to a class now shown to be characteristic of the second and third phases of the Middle Minoan, barely surviving into Late Minoan I a. The sepulchral relics thrown out at the opening of the dromos undoubtedly belong to Middle Minoan III. The 'Royal Tomb' itself supplied a very fine series of Late Palace vases (L. M. II); but here, too, conflicting data were apparent in the early character of stone vessels of the Eighteenth Dynasty, Middle Kingdom and even a strong tradition of Fourth Dynasty influence. Ritual signs on the blocks themselves correspond, it had already been noted, with those on the earliest structures of the Late Palace at Knossos. It is now known that the practice of incising such signs on Palace blocks was not followed in Late Minoan II. The makeshift character of the concluding palatial phase does not fit in with the fine architectural construction and massive masonry of the Royal Tomb. A viaduct and bridge on the east slope of the Palace site have now afforded a parallel in splayed blocks like the Isopata vaulting. These structures belong to an even earlier phase than the Isopata tombs, and centre rather in Middle Minoan II. The use of the horizontal arch and vault, in fact, go back to the earliest Palace period, or approximately the twentieth century B.C. As a result of the last campaign at Ras Shamra, it may be taken as demonstrated that there was an actual Minoan colonization there so early as the second Middle Minoan period, which was already reacting on north Syrian culture. It will be seen from the Knossian evidence that the parallel between the vaulted tombs and those of Ras Shamra (Ugarit) ought to be carried back to that epoch.

Otomi of Central America

THAT important, but little-known, group of Indians of Central America, the Otomi and their affinities, are the subject of a study by Dr. Jacques Soustelle ("La Famille Otomi-Pame de Mexique centrale". *Tr. et Mém. de l'Inst. d'Ethnol. Univ. de Paris*, 26; 1937). This study embodies the results of investigations, undertaken at the suggestion of Dr. Paul Rivet, lasting over a period of two years and some months. Conclusions are based mainly on the linguistic evidence, as culture has been affected profoundly by European contacts, while language to a large extent has retained its original characteristics. At the same time the evidence of history and of the geographical distribution of the tribes supports the findings from linguistic evidence, and the data of physical anthropology, ethnography and recorded history have therefore also been taken into account. The Otomi—the name is Aztec or Nahuatl—were regarded by the early Spaniards as a typical mountain-dwelling tribe; and this still holds good. Of seven divisions here recognized, four are in the *terras frias*, the cold lands of high altitude, and three in the *terras templadas*, the temperate lands, while no Otomi are found in the *terras calientes*, the low-lying hot lands of the coastal area. In 1921, the Otomi numbered 210,873 and the four related tribal groups in all just over 67,000. Briefly, it would appear that in the pre-Cortesian era the members of this linguistic family belonged to two groups of very different cultural level, the first being sedentary agriculturists, the second, to which belonged the Chichimecs, nomad or semi-nomad hunters. According to Sahagun the Otomi cultivated maize and agave and were makers of the drink *pulqué*. They lived in villages. The standard of living of the food-gathering hunting tribes was poor. They lacked salt and the Chichimecs lived in caves. The Otomi originally were without pottery. It was natural that to the Aztecs, who conquered and drove them to the hills, excluding them from the stream of cultural development, the culture of these tribes should appear low.

Osteology of *Varanus*

Varanus monitor is a large and well-known lizard; but in spite of this, the accounts of the skull given in many of the ordinary text-books are often incomplete or actually incorrect. This deficiency is made good by K. N. Bahl (*Rec. Indian Museum*, July 1937), who has provided a very full and well-illustrated account of the skull. It is well ossified, but important cartilaginous structures still remain. It is truly streptostylic, that is, the quadrate bone is freely movable at all its articulations. It is metakinetic, and the occipital segment is movable on the maxillary segment at four places, not three as is sometimes stated. The foramen internum is present, but it transmits the sixth cranial nerve and not a branch of the internal carotid artery as was supposed by Siebenrock, its discoverer. The soft parts, nerves and blood vessels related to the skull have been fully taken into account in the description.

Insects Affecting Stored Products

IN the *Annals of Applied Biology* of November, 1937, Mr. H. Hayhurst gives an annotated survey of the species of insects, etc., found by him on the L.M.S. Railway during the past ten years. They were found infesting commodities stored in warehouses and in transit, etc. He mentions that all imported commodities and those liable to infestation were examined prior to transit and to being warehoused. The great majority of insects commented upon are Coleoptera (beetles), with some seven species of moths and a few mites, etc., and the greater number of them are cosmopolitan pests, well known to economic entomologists. An enormous variety of different substances may be infested by a single species of insect; this is especially noticeable in the case of the beetles *Ptinus tectus*, *Tribolium confusum* and *castaneum*; the moths *Borkenhausenia pseudospretella* and *Endrosis lactella* and the mite *Tyroglyphus farinæ*. An article of this kind serves to emphasize the fact that too little attention is paid to pests of stored products in Great Britain. Furthermore, in the event of any large accumulation of such products becoming necessary as a reserve in the event of war, heavy losses from pests are certain to supervene unless proper measures are adequately formulated beforehand. Among the various means of protection one of the most important is the construction of properly built granaries and stores which readily admit of the sterilization of the contained products when necessary.

Rock-Burrowing Organisms and Coral Reefs

MR. G. W. OTTER describes many interesting facts with regard to rock-borers in his monograph "Rock-Destroying Organisms in Relation to Coral Reefs" (Great Barrier Reef Expedition 1928–29, 1, No. 12; 1937. British Museum (Natural History)). Most of these are molluscs, but Crustacea, worms, sponges, and to a certain extent echinoderms and some plants burrow more or less into the corals; but molluscs are by far the most important in actual destruction. The mode of life is varied and the different forms may bore by mechanical means as in *Petricola*, *Gastrochœna*, *Tridacna* and *Arca*, or may use some form of acid as in *Lithophaga*. The barnacle *Lithotrya valentiana* is also a mechanical borer. The formation of the burrows is described in detail for many forms, feeding and rate of growth in relation to rock-boring is discussed and also the distribution and ecology of rock-burrowing organisms including geological nature of the rocks available for attack. Finally the author describes the effects of rock-burrowers in relation to coral reefs. There is no doubt that these various factors of destruction affect the reefs to such an extent that it is often difficult for them to hold their own against them; many are completely destroyed and few, if any, are appreciably growing. Mr. Otter's work gives us a good summary of all the causes of such destruction.

Trout-marking in Massachusetts

ON the populous Atlantic seaboard of the United States the streams are so intensively fished that a stock sufficient to meet the needs of anglers can be kept up only by the frequent and extensive introduction of trout of legal size. These may be placed in the river in autumn or in spring, and doubt has existed as to which is the more satisfactory time. To settle the question, if possible, 2887 rainbow trout and 4830 brown trout, 6–10 inches long, were marked by the internal tagging method, and released, some in November and some in the last week of March. The trout season opened on April 15 (R. A. Nesbit and J. A. Kitson in *Copeia*, 168; 1937). The recoveries indicate that if fish are planted in the autumn, the over-winter losses are so great that five times as many fish are required to provide a given catch as are needed if the fish are held in the hatchery until spring. Against this advantage must be reckoned the cost of keeping the fish in a hatchery over winter, and the less easily reckoned consideration that autumn fish are said to yield better sport. In the course of their experiments, the authors discovered that the method of internal tagging with a celluloid belly tag, or with a soft rubber tag which they later substituted for the celluloid tag, was not satisfactory for trout, and they recommend that in future experiments the jaw method of marking described by Shetter in 1936 and 1937 should be adopted.

Effect of Bio-azotized Peat on Plants

BIO-AZOTIZED peat differs from ordinary organic manures, such as farmyard manure, in that the microflora is mostly ærobic, cellulose and nitrogen-fixing bacteria being especially prominent. Again, the latter build up nitrogen compounds from free nitrogen, while, in most organic manures, complex nitrogenous compounds are broken down. The activity of the microflora, in bio-azotized peat, results in a multiplication of nitrogen-fixing organisms, an accumulation of nitrogen, and a conversion of the unavailable portion of the peat into more readily assimilable compounds. Experiments have recently been carried out by Makinov, both in pots and in the field, to test the effect on yield and nitrogen content of crops; in order to reduce the number of unknown factors, a 'synthetic' soil was used in one series of pot trials ("Effect of Bio-azotized Peat on the Growth and Nitrogen Content of Plants. *Nature* (translated title), 140, 51–57, August 1937. Leningrad). The bio-azotized peat proved as effective in small doses as mineral nitrate in raising yield, and, in larger application, proved more effective than the latter; applications representing less than 2 per cent of the weight of soil did not yield satisfactorily because of the insufficiency of energy-providing material for the activities of the cellulose and nitrogen-fixing bacteria. The bio-azotized peat raised the nitrogen content of the crop by an unexpectedly large amount, as compared with unactivated peat; thus, with equal quantities of both, the percentage of nitrogen in the dry matter of oat plants amounted to 1·537 in the former and 1·061 in the latter. This large increase, of the order of 50 per cent, may be contrasted with the increments of the order of 5–10 per cent noted in Great Britain in grasses manured with nitrogen.

Control of Insect-Transmitted Virus Diseases

Two virus diseases attack the henbane plant, *Hyoscyamus niger*, which is grown for the preparation of pharmaceutical compounds. Both viruses are transmitted from diseased to healthy plants by the aphid *Myzus persicae*. Dr. Marion A. Watson (Hamilton) (*Ann. App. Biol.*, 24, No. 3, 557-573, Aug. 1937) has experimented upon the possibility of controlling the spread of the maladies by eradicating the insect vector. The aphid can be controlled by treatment with nicotine sprays, and its removal substantially reduced the incidence of the virus. There was, moreover, an increase of 30 per cent in the third crop of leaves, harvested in the second year of growth.

Take-All Disease of Wheat

'TAKE-ALL' is the expressive name given to a disease of wheat and other grasses, caused by the fungus *Ophiobolus graminis*. The attacks of this organism are often very severe, and result in the production of grainless heads of corn. Mr. Geoffrey Samuel has lately summarized our knowledge of this disease (*J. Mins. Agr.*, 44, 3, 231–241, June 1937). He describes the symptoms and life-history of the fungus in detail, and discusses the persistence of mycelium in the soil, after the removal of a diseased crop. It has been shown that soil conditions affect the longevity of the fungus to a considerable degree. The disease is more to be feared on light soils than on heavier ground; it is favoured by soils with alkaline reaction, and flourishes where organic matter is abundant. Many wild grasses are also attacked, but oats and rye-grass are resistant crops which may follow wheat in the rotation. Other methods of control are set forth in the paper.

Formation of Large Hailstones

AT the meeting of the Royal Meteorological Society held on November 17, Mr. T. E. W. Schumann gave a mathematical analysis of the generally accepted theory that the formation of large hailstones is due to the constant collection by the stone of supercooled water drops that lie in its path. The problems that received particular attention were, first, how it is possible for a hailstone to remain suspended long enough in the clouds to collect enough drops to enable it to reach the very large size sometimes attained, 10 cm. and more in diameter, and, secondly, how the hailstone gets rid of the latent heat of condensation of the supercooled water that freezes on it. It was shown that the main factors that determine the size to which a hailstone grows are its average density (which will depend on the amount of air entrapped in it), the height at which the nucleus is formed, the average upward velocity of the air and the amount of liquid water present in unit volume of air in the regions with temperature below 0° C. The connexion between these various factors was shown by a series of graphs. It was found that the probable values of the water content and of vertical velocity are sufficient to account for hailstones at least 8 cm. in diameter. The disposal of the latent heat was examined in considerable detail, and it was demonstrated that this heat can be disposed of partly by the absorption of heat from evaporation from the surface of the hailstone and partly by conduction to the surrounding air, although in the neighbourhood of 0° C. the mechanism of heat disposal is reduced in efficiency to such an extent that the rate of growth and therefore the final size of the stones is more restricted than at lower temperatures.

Higher Oxides of Lead

As is well known, the preparation of pure lead dioxide, PbO_2, is very difficult. This oxide is present in the positive plate of the accumulator, and X-ray examination has given evidence of highly characteristic distortion in the lattice under certain conditions. It has been shown that the tetragonal lattice persists from PbO_2 down to $PbO_{1 \cdot 66}$. G. L. Clark, N. C. Schieltz and T. T. Quirke (*J. Amer. Chem. Soc.*, 59, 2305; 1937) have examined the formation of PbO_2. By heating lead dioxide, sodium hydroxide, water and a trace of manganese dioxide in a bomb, crystals of Pb_2O_3, Pb_3O_4 and a new oxide Pb_5O_8 have been prepared at the temperatures of 260–275°, 355–375° and 295–310°, respectively, the compounds being identified by microscopic examination and X-ray diffraction patterns. The crystals supposed to be PbO_2 obtained by this process were shown to be Pb_2O_3 mixed with PbO_2. It appears, therefore, that this process does not give pure lead dioxide.

Stereochemistry of Cobalt and Manganese

THE ion $CoCl_4$ in Cs_3CoCl_5 has been shown to possess tetrahedral configuration, whilst the existence of two forms of $Co(NH_3)_2Cl_2$ suggests that they are *cis*- and *trans*-isomers of plane configuration. Stereochemical studies of the two forms of $CoPy_2Cl_2$ (Py = pyridine), which are monomolecular, have been made by E. G. Cox, A. J. Shorter, W. Wardlaw and W. J. R. Way (*J. Chem. Soc.*, 1557; 1937). The X-ray measurements show that in the α-compound the four groups linked to the central cobalt atom have a *trans*-planar configuration. The corresponding compound with manganous chloride is isomorphous with the α-dipyridino-cobaltous chloride, and in this compound the four covalencies of bivalent manganese also have a planar configuration. The β-dipyridinocobaltous chloride is isomorphous with the only known forms of dipyridinocobaltous bromide and iodide, and their stereochemistry is still uncertain. These results are of interest in providing a definite example of a metal, cobalt, in the same valency state which has both planar and tetrahedral quadricovalent derivatives.

Artificial Radioactivity Produced by α-Particles

THE cyclotron method of accelerating particles makes possible the production of energetic α-particles in numbers equivalent to the particles from many grams of radium, and the energy of the cyclotron particles may be considerably higher than those from radioactive elements. L. N. Ridenour and W. J. Henderson (*Phys. Rev.*, 52, 889) have used a beam of 9 Mev. α-particles to produce artificial radioactive elements by bombarding B, N, Mg, Al, P, Cl, Cr, Ni, Co, Cu, As, Br. The majority of the radioactive nuclear species produced are already known, having been produced by other nuclear reactions with neutrons. In most cases, the radio-elements were identified by chemical methods, and the nuclear reactions were found to involve the absorption of an α-particle with emission of a proton or more commonly a neutron.

Meteors at Great Heights

MR. J. G. PORTER has written a paper (*J. Brit. Astro. Assoc.*, 48, 2, December 1937) which is a continuation of others previously published, in which the true paths of meteors doubly observed at Stowmarket and Peterborough are given. A large number still remain to be computed, and up to the present Mr. Porter has only been able to deal with those observed up to the end of October 1934. Among the 30 observed in that month at the two stations referred to, there is one of great interest observed on Oct. $15^d\ 23^h\ 31^m$, of magnitude about 5·5. Its heights at the beginning and end are 257 and 248 kilometres, respectively. As there was a very close agreement between the figures for the two observers, the results must be accepted as accurate. The Rev. Dr. M. Davidson pointed out at a discussion of the paper that occasionally such great heights had been found previously, but had always been considered inaccurate. Meteors in the higher regions should throw some light on the conditions of the atmosphere in those parts.

Protection for Telescopes

MR. F. R. CLARK describes (*J. Brit. Astro. Assoc.*, 48, 2, December 1937) how he made and utilized a movable roof to cover an observatory for a 3½-inch refractor, and in the same journal Mr. F. O. Smith describes how he made a garden hut for a 6-in. Wray equatorial for the small sum of £10 10*s*. It is impossible in the limited space to give a summary of these two papers; amateur astronomers are recommended to read them carefully if they contemplate erecting simple and inexpensive observatories.

Ancestry of the Tetrapods

By T. Stanley Westoll, University of Aberdeen

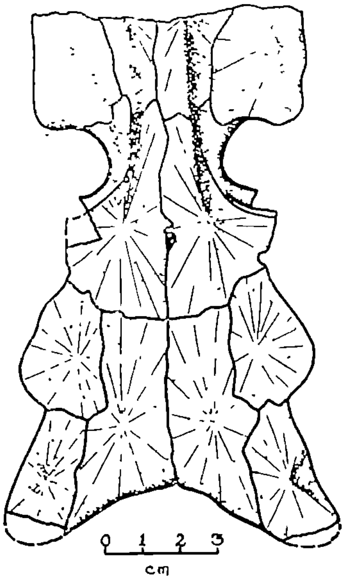

Fig. 1.

Dermal skull-roof of *Elpistostege watsoni*, gen. et sp. nov. The specimen is incomplete anteriorly.

During the last few decades it has become increasingly clear that the Tetrapods were derived from a group of fishes having their closest affinities with the Devonian Crossopterygii and Dipnoi. In 1932, Säve-Söderbergh published a valuable description[1] of some fossils, from the "Upper Devonian" of East Greenland, which afford a valuable bridge between the Crossopterygii and the Carboniferous Stegocephalians. These forms, the Ichthyostegalia, are much closer to the Stegocephalians than to the Crossopterygii in structure. The homology of most of their bones, in terms of the normal Tetrapod skull, is clear; but Säve-Söderbergh, when comparing the Ichthyostegid skull with that of the Crossopterygii, found it necessary to adopt a very cumbersome modification of the terms used in the description of the latter group. The nomenclature adopted had a praiseworthy intention, to indicate the homologies of the comparatively specialized Tetrapod skull on the basis of the structure of generalized fossil fishes. Unfortunately, the nomenclature of the fishes concerned is based on Tetrapod names, which have largely been misapplied in fishes. As a result of this, the Tetrapod parietal and post-parietal were regarded by Save-Söderbergh as "fronto-parietal" and "parieto-extrascapular", and a number of other changes was suggested. Säve-Söderbergh recognized two bones in the place of the Tetrapod pre-frontal, and his attempts to find these elements in higher Stegocephalia[2] have led to further complications. I have suggested[3] that the Tetrapod parietal contains no part of the Crossopterygian "parietal", but is represented in the "frontal" of such a fish as *Osteolepis*; and more recently I have directed attention[4] to the probable errors in homology made by Säve-Söderbergh in the supra- and pre-orbital regions.

During the summer of 1937, in company with Mr. W. Graham-Smith of the University Museum of Zoology, Cambridge, I visited certain Devonian vertebrate-yielding horizons in eastern Canada, including the famous sections at Scaumenac (Escuminac) Bay, P.Q. Among the material acquired from a local collector was a skull-roof, which was only partly exposed and seemed to belong to a Crossopterygian. Preparation has disclosed a

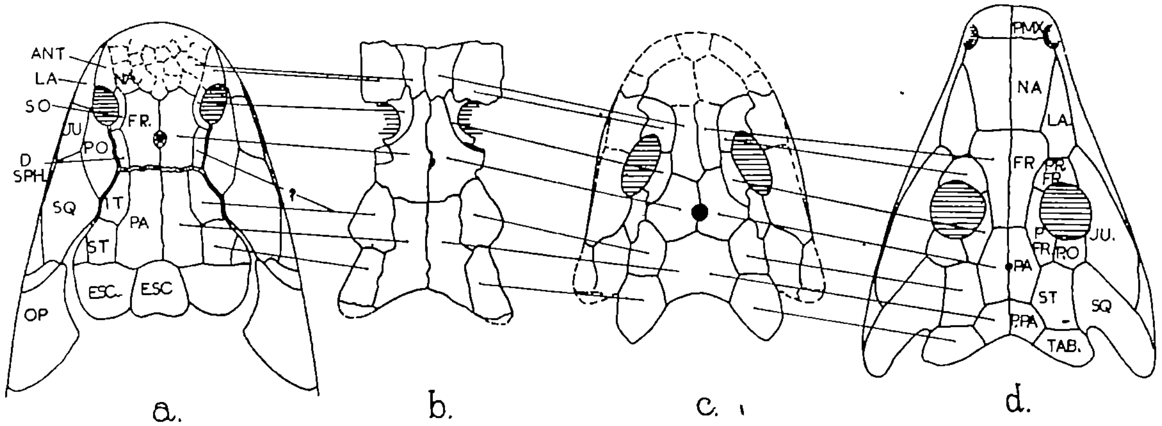

Fig. 2.

Comparison of skulls of (*a*) *Diplopterax* (Mid. Devonian), with Crossopterygian names. (*b*) *Elpistostege* (lowest Upper Devonian). (*c*) *Ichthyostegopsis* (high Upper Devonian or ? early Carboniferous). (*d*) *Actinodon* (Lower Permian), with Tetrapod names. Homologous bones linked throughout series.

ANT., "posterior antorbital"; D.SPH., "dermosphenotic"; E.SC., extrascapulars; FR., frontal; I.T., intertemporal; JU., jugal; LA., lacrimal; NA., nasal; OP., opercular; PA., parietal; P.FR., post-frontal; P.MX., premaxillary; P.O., post-orbital; P.PA., post-parietal; PR.FR., prefrontal; S.O., supra-orbital; SQ., squamosal; S.T., supratemporal; TAB., tabular.

fairly well preserved dermal skull-roof, lacking the snout; it provides a perfect transition between the Crossopterygian and Ichthyostegid patterns of dermal bones.

The bones are exposed mostly from the visceral aspect, and have the arrangement shown in Fig. 1. The bones in front of the orbit are probably flattened out rather more than in life. Between the orbits the skull-roof was markedly concave from side to side, with a sharply depressed median groove. The specimen is clearly a new form and may be named *Elpistostege watsoni*[5], gen. et sp. nov. (from ’ελπιστός, hoped-for; στέγη, a roof. The trivial name is a token of my indebtedness to Prof. D. M. S. Watson). A more detailed description, with an account of other material (some of which may perhaps be referred to this form) will be published elsewhere in a general work on the Scaumenac Bay Devonian fish-fauna by Graham-Smith and myself.

In Fig. 2 the skulls of *Diplopterax* (a primitive Crossopterygian from the Middle Old Red Sandstone, restored by me), of *Elpistostege* (from the lowest Upper Devonian[5]), of *Ichthyostegopsis* (from the *Remigolepis*-series high up in the Old Red Sandstone facies in East Greenland, modified after Säve-Söderbergh), and of *Actinodon* (from the Lower Permian, modified from Lydekker) are compared. There is an unmistakable homology between elements as follows:

Usual Crossopterygian names		Tetrapod names
Parietal	=	Post-parietal
Supratemporal	=	Tabular
Intertemporal	=	Supratemporal
Dermosphenotic	=	Intertemporal
Frontal	=	Parietal
Nasals (posterior)	=	Frontal
Supraorbital	=	Post-frontal
Posterior antorbital	=	Pre-frontal

In most Stegocephalia, as in *Ichthyostega* and *Elpistostege*, the separate intertemporal of such forms as *Trimerorachis* and many Loxommids and Anthracosaurs is apparently usually fused with the supratemporal, though in some cases it may possibly be reduced. The Crossopterygian extrascapulars have apparently been lost in Tetrapods.

It seems clear that the differences between the bone-patterns in the forms figured are, with the exceptions noted above, rather a matter of changes of proportions of the skull than of reshuffled elements or differential fusions such as Säve-Söderbergh suggested. The present study completely confirms my previous revisions of homologies, which were the results of different lines of investigation.

The following points may be noted. (1) The pineal foramen is absolutely homologous in position in all the forms discussed. (2) The single median post-parietal of Ichthyostegids can be paralleled occasionally in Crossopterygii; I have a skull of *Eusthenopteron* showing this feature. It represents a pair of bones in related animals. Analogous cases from other groups could be quoted. (3) The cheek in *Elpistostege* was not united to the table of the skull by suture. (4) It now seems possible that the transverse division of the Crossopterygian cranium is no bar to regarding that group as ancestral to the Tetrapods. The division is a retention of the separate trabecular and parachordal chondrifications of the embryos, perhaps because of some special mechanical necessities of the extremely wide gape in Crossopterygians. (5) Although the Ichthyostegids may not be directly on the line of evolution to the known Stegocephalia, they provide a very good morphological ancestry in many ways. (6) The Stegocephalia quickly lose the primitive appearance of Ichthyostegids, being even more shortened posteriorly, and having the orbits with their surrounding bones moved forwards, so that the primitive pattern tends to be distorted. (7) It now seems likely that the evolution of the Tetrapods from fish-ancestors may have taken place very rapidly in the early Upper Devonian; the state of the paired limbs of *Eusthenopteron* and *Sauripterus*, and the structure of the vertebral column of some Crossopterygian fishes of this period offer a good ancestral type.

These matters will be more fully discussed elsewhere. I wish to acknowledge grants from the Royal Society of London, and the Geological Society, and a Senior Research Award from the Department of Scientific and Industrial Research, which were in force during the visit to Canada. I am also much indebted to my companion in the field, Mr. W. Graham-Smith.

The Science Masters' Association

ANNUAL MEETING

THE thirty-eighth annual meeting of the Science Masters' Association, held on January 4–7 in London, was attended by more than six hundred members. There were as usual exhibitions by leading publishers and manufacturers of scientific apparatus and the customary exhibition of apparatus devised and made by members themselves.

The meeting opened with the presidential address by Sir Cyril Ashford. Sir Cyril was one of the founders of the Association and was its first secretary, and, rather naturally, contrasted the state of science teaching as he knew it in the early days of the Association and as he found it to-day. The whole address was of a delightfully domestic nature, and at the conclusion Sir Cyril was thanked by two of his fellow pioneers in the forming of the Association—Mr. Archer Vassall and Dr. T. J. Baker.

A new feature of the meeting was the holding for the first time of a lecture on "Science and Citizenship". Since the last London meeting, the Association has accepted the trusteeship of certain funds the purpose of which is to endow a lecture on the subject named. The Association was fortunate to obtain Sir Richard Gregory as the first lecturer under the scheme, and a crowded attendance listened to an extremely interesting and informative lecture.

Sir Richard began by referring to the loss sustained by the Association in the deaths of Lord Rutherford and Prof. H. E. Armstrong, whom he described as closely similar in their devotion to science, but markedly different in their personal characteristics and in the scope and manner of their work. Lord Rutherford was a supreme example of a modern scientific investigator, fertile in conception, ingenious in experiment, with brilliant insight into the relation between causes and consequences of phenomena in a sublime field of physical inquiry. Prof. Armstrong, on the other hand, though his original work belongs mainly to the field of organic chemistry, had extensive interests in much wider fields such as geography, geology, natural history and agriculture. He took a great and active interest in educational matters, though he was critical—and sometimes caustic—in his comments on science teaching and science teachers.

The comparison of these two great men of science led Sir Richard to his main theme, which was that the scientific worker must not subordinate his citizenship to his science. If he does, society may itself take measures to prevent the perversion of science to destructive purposes. Our national leaders and administrators need wide knowledge and keen foresight to enable them to make the most effective use of the scientific forces which are shaping the conditions of modern life. Science can render the fullest service to the community by harnessing the relations between the scientific workers and the general citizen so that a nobler type of citizenship becomes possible, adequate to defend us against the dangers to which civilization is exposed.

Education may be defined as the deliberate adjustment of a growing human organism to its environment, and therefore preparation for citizenship must involve instruction in the principles of human biology: a course of general biology should open and close with man in the centre of the picture. In schools and universities there is still a tendency to teach science only as a specialized study and not as an essential part of a general education. As science is responsible for the industrial developments and economic changes which have caused violent disturbances in our social structure and provided the means by which civilization may commit suicide, it has a right and a duty to occupy a position of authority in the government or control of the powers it has created. Men of science are citizens as well as scientific workers, and they are beginning to realize their special responsibilities for securing that the fruits of scientific knowledge are used for human welfare. It would be a betrayal of the scientific movement if scientific workers failed to play an active part in solving the social problems which their contributions to natural knowledge have created. They must promote the extension of the application of scientific method to the consideration of social, economic and political questions, so that accurate knowledge may be obtained upon which sound conclusions may be based and progressive policies established.

Other lectures at the meeting were varied in type. Prof. P. M. S. Blackett talked on cosmic rays; Mr. W. D. Seymour on the heating, lighting and ventilation of schools; Dr. Sherwood Taylor on the origins of chemistry; Prof. Allan Ferguson on capillarity; Mr. J. Z. Young on "Brain Waves" (dealing with the regular rhythmical changes of electrical potential recorded for numerous parts of the brain); Mr. A. Rodger talked on vocational guidance and Dr. C. C. Paterson on the appraisement of lighting.

Two discussions were also held. The first dealt with the problem of laboratory assistants in schools. The Committee of the Association is in the course of preparing a memorandum on this matter, and the opinions expressed at the meeting will be incorporated therein and will be published. The second discussion dealt with the relations between school and university science teaching. Discussions of this type almost invariably lead to the difficulties of university scholarship examinations, and this was no exception.

At the business meeting, Prof. James Gray of Cambridge was elected as president for next year. In succession to Mr. F. R. Snell (Eastbourne College), Mr. W. Ashhurst (Stretford Grammar School), Mr. L. G. Smith (Trowbridge Grammar School) and Dr. W. G. Davies (Royal Grammar School, Newcastle), who retired from the Committee, the meeting elected Mr. J. W. Cottingham (Barnsley), Mr. R. E. Williams (Oxford), Mr. G. Fowles (Latymer Upper School) and Mr. R. P. Ayres (Leys School). Mr. S. V. Brown (Liverpool Institute) was re-elected general secretary, Mr. B. M. Neville (William Ellis School), honorary treasurer and Mr. W. Ashhurst (Stretford) as annual meeting secretary.

S. V. B.

The Mathematical Association

ANNUAL MEETING

AT the annual meeting of the Mathematical Association, which was held at the Institute of Education, London, W.C.1, on January 4 and 5, Prof. E. H. Neville, in taking the chair, explained that he occupied that position in consequence of the sudden death of the president, Prof. L. N. G. Filon, which took place on December 29. After the members had stood in tribute to the late president, the business meeting took place, at which Mr. W. Hope-Jones was elected president for the following year. The existing officers were all re-elected and Miss M. A. Hooke and Mr. F. J. Swan were elected to the Council in succession to Miss G. K. Stanley and Mr. C. T. Daltry, who retired under the regulations. A presidential address, prepared by Prof. Filon previously to his illness, was read by Prof. G. B. Jeffery. The address, which was entitled "Mass and Weight in Newtonian Mechanics", and contained an analysis of the fundamental ideas of dynamics, will be printed in full in a forthcoming issue of the *Mathematical Gazette*.

Prof. D. R. Hartree then spoke on "The Mechanical Integration of Differential Equations". Prof. Hartree referred first to the need for mechanical contrivances for carrying out extended calculations in pure and applied science. So far as purely arithmetical calculations are concerned, this need has been largely met, but the use of machinery for dealing with problems relating to rates of change is not yet widespread. He explained, illustrating by lantern slides, the mathematical and mechanical principles of the differential analyser, a type of machine invented by

Dr. Bush of Boston, U.S.A. Only four complete machines are at present in existence, two others being in the course of construction. He showed a number of slides illustrating the machine in use at the University of Manchester and explained that this machine contains some devices which represent an English improvement on the American model, notably in regard to the solution of equations involving a time-lag. Some results, including those of problems arising from practical and technological sources, were shown.

At the first session on January 5 a discussion on "The Relative Value of Pure and Applied Mathematics" was opened by Dr. W. G. Bickley. Dr. Bickley put forward a case for the wider inclusion of applied mathematics in the school curriculum. He laid stress on the fact that the performance of university students in pure mathematics is invariably superior, on the average, to their performance in applied mathematics. Mr. C. G. Nobbs, while agreeing with Dr. Bickley, pointed out that this discrepancy of results may be due, at least in part, to difficulties inherent in the experimental nature of the subject and the close interplay of principles involved. Miss K. I. Sayers pleaded for a closer association between physics and mathematics and issued a warning against premature specialization to the exclusion of literary and artistic subjects.

Mr. N. R. C. Dockeray read a paper on "The Law of Quadratic Reciprocity". Mr. Dockeray first gave an introductory series of results on quadratic residues and then passed to the consideration of Gauss's Law. He gave an exposition of the third of the six proofs which Gauss constructed. This proof (as modified by Eisenstein) can be cast into a geometrical form suitable for discussion with a Sixth Form. Mr. N. M. Gibbins read a paper on "The Feuerbach Quadrilateral", namely, the figure formed by the four tangents at the points where the nine-points circle touches the inscribed and escribed circles. The subject was approached by areal co-ordinates, and many interesting and elegant results were given.

In the afternoon, at a crowded meeting, Mr. M. Black spoke on "The Relevance of Mathematical Philosophy to Mathematical Teaching". He defined mathematical philosophy as an attempt to analyse the nature of mathematics and its relation to other branches of knowledge. Mr. Black outlined in some detail the system of symbolic logic proposed by Boole and, after referring to other systems, dealt with some famous paradoxes arising out of the attempt to construct such systems. The attempt to avoid, or explain, these paradoxes led Russell to the theory of types. Mr. Black demonstrated how, if this were adopted, certain types of mathematical proof would be rendered invalid and pointed out that these considerations all seem to point to the fact that mathematics would be for ever an 'unfinished system'.

The last meeting was devoted to a discussion on "Teaching the Complete Duffer". This was opened by Mr. B. L. Gimson, who denied the existence of a *complete* duffer. He said that in the attempt to rouse the dormant interest of backward pupils in mathematics, one should appeal to both curiosity and utility. In the former case he stressed the use of magic squares, dissection puzzles and historical considerations, while the latter might well lead to a treatment of such topics as accounts, arithmetic of citizenship, insurance, etc. He emphasized the need for small classes in this work. Mr. F. C. Boon stated that the 'duffer' as well as the brilliant boy ought to have a 'fair deal'. For this purpose 'duffer' classes must be small, their pace slow and their atmosphere right, so that these children may not be deterred from asking questions which might appear obvious by the fear of ridicule. He referred also to the difficulties arising out of the misinterpretation of common words.

Dr. F. H. Dodd commenced by stating that he approached the problem from the angle of the psychologist. Cases of 'duffers' may be attributed to (*a*) educational or environmental failures, (*b*) emotional disturbance. He went on to consider various types of these failures, illustrating his remarks by comments on cases from his own experiences. He added some interesting remarks on the discovery of the precise 'point of failure'. In cases of emotional disturbance, he said that he had frequently noticed that mathematics is the first subject to be affected. An interesting discussion followed.

A publisher's exhibition was held in connexion with the meeting. A full report of the proceedings will be published in later issues of the *Mathematical Gazette*.

Thyrite Surge Diverter

WHEN a lightning flash takes place near overhead lines, it starts an impulsive rush of electricity in them which, unless it is diverted in its path, may damage or even smash costly machinery with which it is connected. Electricians, first in connexion with communication circuits and afterwards in connexion with power transmission circuits, have sought for many years for a substance which is an insulator at the working pressure but at high pressures is a conductor. Connecting a cylinder of this substance between an overhead conductor and earth does not interfere with the ordinary working of the line, but when a surge of electricity raises the pressure the conducting power of the substance leads the surge safely to earth and so protects the machinery. These devices were formerly called 'lightning arresters' but are now known as surge diverters.

The discovery of thyrite provided the desired material. It is a dense, homogeneous inorganic compound of a ceramic nature, perfectly stable, mechanically strong and is an insulator at one voltage and an excellent conductor at a higher voltage. Its electrical resistance increases 12·5 times each time the voltage is doubled. It appears to conform to this law indefinitely without change, regardless of the rate at which the voltage is applied for either continuous or alternating pressures or fast impulses. In a list (Thyrite Surge Diverters, No. H. 4506–1) issued by the British Thomson-Houston Co., Ltd., of Rugby, a descriptive account of these diverters is given for alternating current circuits not exceeding 220,000 volts working pressure.

A complete diverter consists of a number of standard size units stacked in series, the number depending upon the voltage rating. Each unit has a normal rating of 11,000 volts and has its own built-in series-gap. It is 11 in. in diameter, 15 in. high and weighs 75 lb. Cathode ray oscillograms are shown which show the impulse protecting characteristics of the standard 11,000 volt unit. When the crest of the impulse wave is 40,000 volts the insulation breaks down. The impulse voltage attending a 1,500 ampere surge current across the diverter unit is only 34 kv. crest. The surge voltage permitted by the thyrite diverter increases in direct proportion to the number of diverter units from line to earth.

Science News a Century Ago

Prof. Moll

IN various papers and in the annual report of the Royal Astronomical Society are to be found notices of Prof. Moll, of Utrecht, who died at Amsterdam on January 17, 1838. Moll was born on January 18, 1785, and as a youth spent some time as a clerk in a business house in Amsterdam, his native place, devoting his leisure to the study of mathematics and astronomy and other subjects. When about twenty-one years of age, his father allowed him to relinquish business and he became a student first at Amsterdam under van Swinden, and then at Utrecht and Paris, and in December 1812 was made professor of mathematics and natural philosophy in the University of Utrecht. While holding this post he was placed in charge of the "Waterstaat" on which fell the responsibility of preventing inundations, and also had care of the chronometers for the Navy.

In 1824 Moll contributed a paper to the *Philosophical Transactions* on the velocity of sound, and in 1831 published a comparison of British, French and Dutch weights. That same year he published a pamphlet entitled "On the Alleged Decline of Science in England", in answer to Babbage's work "Reflections on the Decline of Science in England, and on Some of its Causes". Three years later he received an honorary degree from the University of Edinburgh and was also made an honorary freeman of the city. In 1835 he was charged by the King of Holland to make a series of observations on the tides around the Dutch coast, his report being sent to Whewell.

Henry Earle (1789-1838)

HENRY EARLE, one of the most distinguished surgeons of his time, who was born on June 28, 1789, came of a celebrated medical family, his father, Sir James Earle, being surgeon to St. Bartholomew's Hospital and a skilful lithotomist, and his maternal grandfather the illustrious surgeon Percival Pott. From an early age, he showed a striking predilection for surgery, so that at the age of sixteen years he became an assistant to his father. He qualified in 1808, when he was made house surgeon at St. Bartholomew's Hospital, and three years later set up in independent practice. In 1813, he won the Jacksonian prize of the Royal College of Surgeons for an essay on diseases and injuries of nerves, and in 1819 he was awarded two prizes by the Royal Society of Arts for the invention of a bed for fracture of the legs.

In 1815 Earle was appointed assistant surgeon to St. Bartholomew's Hospital and twelve years later full surgeon on retirement of Abernethy, when he started a series of clinical lectures which continued until his death in 1838. In 1822 he was elected fellow of the Royal Society. In 1833 he was appointed professor of anatomy and surgery at the Royal College of Surgeons. Two years later he was elected president of the Royal Medical and Chirurgical Society and held this office for two years. On the accession of Queen Victoria in 1837 he was appointed surgeon-extraordinary to Her Majesty. In addition to twelve surgical papers in the *Medico-Chirurgical Transactions* and two in the *Philosophical Transactions*, he published a book entitled "Practical Observations in Surgery" in 1823. He died in his fiftieth year, on January 18, 1838.

A Severe Frost in England

IN January 1838, Airy visited Sedgwick at Norwich, whence he wrote to his wife on January 21: "I do not know what degree of cold you may have had last night, but here it was (I believe) colder than before—thermometer close to the house at 3°." According to the "Annual Register" for 1838, the frost set in on the evening of Sunday, January 7, and continued for more than a fortnight. On January 20 at 6 a.m. the thermometer at the receiving-house of the Royal Humane Society in Hyde Park stood at $-3°$ F. and on January 20 and 21 the Thames was completely blocked with ice, "the navigation was stopped *in toto*, and a spectacle which has not presented itself for many years was observed. Several men passed over the ice in safety from one shore to the other, below bridge, and during the whole of the day there was a regular communication between the vessels lying in the middle off the Tower and the shore over the ice. . . . There was a complete block at Blackwall. . . . No steamers came in or went out of the river on the 20th and it appears that the various reaches below Greenwich were as full of ice as the upper and lower pools. Even at Gravesend the business was suspended. . . . On Thursday the 25th a sheep was roasted whole on the ice near the centre of the river, near the Suspension Bridge, Hammersmith. Three skittle-grounds were formed on the ice opposite the east corner of the Custom House, and the game was played by great numbers all day. . . ."

The Continental Universities

IN the January number of the *Gentleman's Magazine*, 1838, was an article entitled "Statistical Accounts of the Continental Universities", by a German.

When speaking of the Russian universities, it was said: "Writers have boasted that the Russians are making rapid progress in science, owing to the excellent management of the government with respect to the universities; but a proper description of, and an examination into, the systems by which they are upheld would lead to a very different result." In the six universities of Russia the number of students was: Charkow 342, Dorpat 536, Kasan 252, Kiew 120, Moscow 419 and Saint Petersburg 285. In these several institutions are employed and paid by the Government no fewer than three hundred and thirty-eight professors and functionaries . . . the latter, however, we may state to be no better than spies, each holding his particular office, and all appointed for the special purpose of keeping a strict guard over the political dispositions of the students; a system that cannot be too much censured."

Referring to the German universities, which boasted a total of about 16,000 students, the writer said: "In our sketch of the German Universities, we shall have no difficulty in drawing a picture which will display a very remarkable contrast to that already before the reader. . . . Germany is *par excellence* the land of universities, and famous not only for their numbers but also their good organisation." At that time the number of students at Berlin was 1746, at Munich 1300, at Göttingen 823, at Breslau 768, at Bonn 701, at Tübingen 664 and at Heidelberg 456.

Societies and Academies

Dublin

Royal Dublin Society, November 23.

H. H. Dixon and L. A. T. Ballard: A simple method of showing tension in the sap of a plant. If a branch of *Vitis striata* is clamped sufficiently tightly to close the vessels and to crush the cells around them, and is then cut off from the plant below the clamp and allowed to wilt completely, on afterwards cutting the stem above the clamp under water, the recovery of the shrivelled leaves and sagging petioles will be a matter of hours. Transpiration has caused the water-columns to break with the formation of bubbles in the vessels, and on cutting, atmospheric pressure partially refills the vessels so that the capillary forces around the remaining bubbles lead to their gradual complete solution. The water supply is re-established, and the observed tardy recovery brought about. If, however, the clamped stem is cut under water as soon as the petioles have sagged into a vertical position, but before the leaves show shrivelling, an immediate recovery will be noted, being complete within 10–12 minutes of the cutting. That complete recovery is not instantaneous seems to be due to delay in the release of the tension, owing to the resistance experienced by the water in entering the cut tracheæ, and to semi-permanent deformation of the tissues. The fact that the movements of the petioles at successive nodes are simultaneous is further justification for regarding these immediate movements as due to the release of tension in the water-columns.

J. H. J. Poole: The theoretical efficiency of cylindrical ionization chambers when used for estimating radon by α-particle counting. When finding the radioactivity of rocks by counting the α-particles due to the resultant radon and products of rapid decay, the number of particles per min. per 10^{-12} gm. of radium may be found by direct experiment. A useful check is afforded by comparing this with the theoretical value. This depends on the dimensions of the chamber, the minimum range within the chamber which the counter can detect, and the distribution of the active deposit. By the use of approximate methods of integration, it is shown that the efficiency of the chamber used should be about 58 per cent. The experimental figure is only slightly below this, indicating fairly complete de-emanation of the rock in the furnace used.

December 14.

Robert McKay: Conidia from infected bud-scales and adjacent tissue as a main source of primary infection with the apple scab fungus. A definite relation was shown to exist between the severity of apple scab on the trees in 1936, and the number of infected buds occurring in the dormant season, and also between the number of such infected buds and the outbreak and development of the disease in 1937. Such centres of infection explain the appearance of apple scab in the spring of the year on varieties like Bramley's Seedling, in the absence of both scabbed wood and dead over-wintered leaves.

Paris

Academy of Sciences, November 29 (*C.R.*, 205, 1021–1112).

Lucien Cayeux: The anomalies of the structure and composition of the Albian phosphates of the Paris basin, and some consequences.

Georges Giraud: New properties of certain equations in which principal values of integrals appear.

Marc Krasner: The number of superbodies of a given degree of a body of p-adic numbers.

W. Kozakiewicz: The necessary and sufficient conditions of stochastic convergence.

Lucien Godeaux: The points of diramation of multiple algebraic surfaces.

David Wolkowitsch: The role of the quadrics of inertia in the theory of elliptical co-ordinates.

Georges Kurepa: Monotone transformations of partially ordered ensembles.

Alberto Gonsalez Dominguez: The integrals of Laplace.

Isaie Maximoff: A continuous and essentially increasing function.

Jacques Solomon: The quantum mechanics of systems of electrified particles.

Hervé Fabre: The displacements of the nodes and apsides in planetary systems.

René Lucas: The radiation tensions of transversal waves of inertia and of viscosity of liquids.

Aurel Potop: Contribution to the study of a method for the comparison of the specific heats of gases at temperatures much higher than the surrounding temperature.

Ouang Te-Tchao and André Langevin: The state of equilibrium between large and small ions in a gas.

Fernand Gallais: The magnetic properties of the mercury double iodides. Mercury keeps its usual diamagnetism in the double iodides. The view of P. Pascal that these salts may be paramagnetic is not confirmed by these experiments.

Henri Muraour and Albert Michel-Lévy: A new method for obtaining the spectra of metals. The pulverization of a metal in contact with a powerful explosive gives high temperature spectra closely connected with Anderson spectra obtained by the exploded wire method.

L. Herman and Mme. Herman-Montagne: Remark on a possible interpretation of the bands of ozone.

Serge Nikitine: Theoretical considerations on the dichroism of flow.

Jean Crussard and Serge Gorodetzky: Stimulation function of the nuclear reaction Be(α, n). The possibility of determining the mass of the neutron by a new method. The method is based on the disentegration of boron by neutrons slowed down in paraffin.

Mladen Paić: The action of dilute alkaline hydroxides on cupric hydroxide.

Lévy Herman: The polymerization of gases and the equations of state.

Paul Renaud: A new conception of chemical inertia.

Victor Auger: Crystallized molybdenum blue. The exact conditions for the production of the crystals are given: Mo_8O_{23} and Mo_9O_{26} are possible formulæ.

Mlle. Yvonne Garreau: Some addition compounds of the diphenols.

René Truchet: The valencies of carbon.

Jean Wyart: A case of polymorphism by the progressive passage of a crystalline arrangément to a more symmetrical one, observed on leucite.

Robert Laffitte: The Trias and Lias of Menaa in Aurès (Algeria).

Jean Lacoste: The nature of the deep dislocations in the central part of the Prerif (Morocco).

Jean Feldmann and Mlle. Geneviève Mazoyer: The identity of *Hymenoclonium serpens* and the protonema of *Bonnemaisonia asparagoides*.

Georges Déjardin, Albert Arnulf and René Falgon: The atmospheric absorption and the coefficients of absorption of ozone in the visible spectrum.

Antoine de Cugnac: The experimental synthesis of the hairy form of *Bromus sterilis* by double interspecific hybridization.

Marc Simonet: The caryological study of some species of *Cistus*.

Jean Louis Vidal: The primary causes of chlorosis on limestone soils. Experiments supporting the view of P. Mazé, Ruot and Lemoigne that chlorosis on limestone soils is due to an iron deficiency, caused by the precipitation of the iron in an insoluble form by the lime.

André Paillot: New researches on the histophysiology of the fat body and of the ectodermal tissues of the mulberry tree silkworm during the change of skin.

Marc de Larambergue: Pigmentary varieties of *Bulinus* (*Isidora*) *contortus*; their interest in the genetic analysis of fecundation.

Philippe L'Héritier and Georges Teissier: A hereditary physiological anomaly in *Drosophila*.

Emile Rousseau: The isolation of an oxidizing factor from the blood of cancerous patients and of normal subjects. The deficiency of cancerous blood in this factor.

Jean Loiseleur: The mode of action of pepsin. Measurements of the electro-kinetic potential of a protein submitted to the action of pepsin confirms the hypothesis according to which proteolysis is preceded by fixation of the pepsin on the protein.

Jean Le Calvez: The spiral chromosomes of the first schizogonic mitosis of the foraminifer *Patellina corrugata*.

Constantin Levaditi and Aron Vaisman: Anti-endotoxic chemotherapy.

Amsterdam

Royal Academy (*Proc.*, 40, No. 9, Nov. 1938).

E. Cohen, W. A. T. Cohen-de Meester and J. Landsman: Acute tin pest. The presence of small traces of bismuth greatly retards the transformation of white tin into grey tin at – 50° C., but that of small traces of aluminium has the contrary effect.

L. G. M. Baas Becking and E. A. Hanson: Note on the mechanism of photosynthesis.

J. G. van der Corput: Weyl's method in the theory of numbers (2).

R. Weitzenböck: Trivectors (2).

P. E. Verkade, J. van der Lee, A. J. S. van Alphen and M. Elzas: Researches on fat metabolism (8). Feeding experiments on dogs with sodium salts of normal saturated dicarboxylic acids.

A. G. van Veen and J. C. Lanzing: Analysis of provitamins A in blood serum.

G. Broersma: Preliminary records of the velocity fluctuations in a boundary layer before and after the transition to turbulent motion.

J. C. van Hille: Influence of magnesium on the relation between chlorophyll content and rate of photosynthesis.

Miss W. A. E. van de Geyn: Age of the Elsloo beds. The Elsloo conglomerate and the overlying thin glauconiferous sandy bed examined in the excavation of the Juliana canal are of Lower Pliocene age.

J. Schmutzer: Triangular sugar crystals. Some remarkable crystals obtained from sugar solution which had been treated many times with charcoal and filtered. They showed the same crystallographic angles and optical properties as ordinary cane sugar crystals but had an entirely different habit.

J. Roos and C. Romijn: The oxygen dissociation curve of the cow's blood during pregnancy and the dissociation curve of the blood of the new-born animal during the time immediately after birth.

Vienna

Academy of Sciences, November 11.

E. Clar: Structure of the southern Radstädter Tauern. The results suggest the operation of two distinct processes in the formation of this region. The first consisted of folding under high pressure. The second consisted of displacements along planes intersecting obliquely the structural elements formed during the first phase.

J. Pia, S. R. N. and K. S. Rao: *Dasycladaceæ* from the intermediate sedimentary layers of the Deccan trap at Rajahmundry in South India.

W. Fleischmann and Susanne Kann: Rapid test for sex hormones. The Loewe and Voss test for male sex hormone, which uses mitosis of the mucous membrane of the vesicular gland of the mouse as an indicator, has been improved. Colchicin is injected 39 hours after the injection of the hormone. This arrests mitosis at the metaphase, and thus a larger number of mitotically dividing cells are made visible.

A. Steuer: Determination of the species of *Harpacticus nicæensis* Claus.

A. W. Reitz and R. Sabathy: Studies of the Raman effect (80). Nitrogenous substances (9). Nitriles. Nitriles of unsaturated acids and dicyanide.

November 18.

O. Pesta: Freshwater crabs (*Potamonides*) of southern Greece. From the geographical distribution it is concluded that *Potamon fluviatile* is a direct descendant of *P. potamios*.

F. Eirich and R. Simha: Viscosity of solutions.

W. Knapp: Phenyl-(2-methyl-naphthyl-1)-amino-*o*-carboxylic acid.

Washington, D.C.

National Academy of Sciences (*Proc.*, 23, 561–593, Nov. 15).

A. V. Manza: (1) Some North Pacific species of articulated corallines. (2) New species of articulated corallines from South Africa.

S. Chandrasekhar: The stability of the radiative gradients in the interior of a star. A mathematical discussion.

H. B. Tukey: Plant parts of deciduous fruits which give evidence of being favourable for tissue culture. Micropylar region of the integuments at time of full bloom, and entire integuments and placental region of the inner wall of the carpel of the peach excised after full bloom, are easily removed aseptically and develop well on culture media.

A. Gleyzal: Transfinite real numbers.

G. A. Miller: Groups which contain a Hamiltonian subgroup of odd prime index.

A. D. Michal and D. H. Hyers: Differential invariants in a general differential geometry.

Forthcoming Events

Monday, January 17

ROYAL GEOGRAPHICAL SOCIETY, at 5.—A. E. Smailes: "Population Changes in the Colliery Districts of Northumberland and Durham".

Tuesday, January 18

EUGENICS SOCIETY (in the Rooms of the Royal Society, Burlington House, W.1), at 5.15.—Dr. G. F. McCleary: "Population Problems in the British Commonwealth".

KING'S COLLEGE, LONDON, at 5.30.—S. M. Reisser: "Arc Welding Developments and Applications" (succeeding lectures on January 25 and February 1).

Wednesday, January 19

ROYAL MICROSCOPICAL SOCIETY, at 5.30.—Annual Meeting.

Dr. R. S. Clay: "A Review of the Mechanical Improvements of Microscopes in the Last Forty Years" (Presidential Address).

ROYAL SOCIETY OF ARTS, at 8.15.—D. M. T. Morland: "Recent Investigations into Bee-keeping at Rothamsted".

ROYAL METEOROLOGICAL SOCIETY at 7.30.—Annual General Meeting. Dr. F. J. W. Whipple (Presidential Address).

Thursday, January 20

ROYAL SOCIETY, at 4.30.—Prof. D. Keilin, F.R.S. and Dr. E. F. Hartree: "Mechanism of the Decomposition of Hydrogen Peroxide by Catalase".

H. J. A. Dartnall, Dr. C. F. Goodeve and Dr. R. J. Lythgoe: "Effect of Temperature on the Photo-Chemical Bleaching of Visual Purple Solutions".

J. W. Hughes: "The Monaural Thresholds Effect of a Subliminalcontralateral Stimulus".

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

RESEARCH ENGINEERS (grades II and III) to the B B C—The Engineering Establishment Officer, B B C., Broadcasting House, W.1 (January 17)

ASSISTANTS (grade III, male) at the Chemical Defence Experimental Station, Porton—The Chief Superintendent, Chemical Defence Research Department, 14 Grosvenor Gardens, London, S.W.1 (January 19).

ORGANIZER OF AGRICULTURAL EDUCATION in West Suffolk—The Chief Agricultural Officer, Shire Hall, Bury St. Edmunds (January 22)

JUNIOR CHEMIST in the Midland Agricultural College, Sutton Bonington, Loughborough—The Principal (January 24)

PRINCIPAL of the Chesterfield Technical College—The Director of Education, County Education Officer, St. Mary's Gate, Derby (January 31).

ASSISTANT NATURALIST and a BACTERIOLOGIST at the Laboratory of the Freshwater Biological Association, Wray Castle, Ambleside, Westmorland (January 31)

CHEMIST in the Department of the Government Chemist—The Government Chemist, Clement's Inn Passage, Strand, W.C 2 (February 1).

Realistic Social Studies

IN so far as it will be concerned with realistic study of contemporary issues, the new Institute of Economic and Social Research under the direction of Prof. N. F. Hall, the formation of which was announced in NATURE of January 8, is a venture which has the warm support of many scientific workers. The joint contributions of the Halley Stewart Trust, the Pilgrim Fund, the Leverhulme Fund and the Rockefeller Foundation should guarantee enough for starting a modest programme, which will rehabilitate the prestige of social research in Great Britain, if the personnel and problems are wisely chosen.

Thirty years ago the voluminous and pioneer studies of the Webbs, and the foundation of the London School of Economics, aroused high hopes of a new temper of inquiry. The sequel has been disappointing. Since then, social studies in Britain have been dominated by the dreary and barren dialectical tradition of deductive economics. Like astronomy in the medieval universities, political economy in our leading centres of higher education is still following the trail of self-evident principles. This being so, it is not surprising that responsible bodies which administer funds for research have been loth to make large allocations to university departments, or have refused to renew temporary grants such as the Rockefeller subsidy to the London School.

In his recent farewell address to the latter, Sir William Beveridge compared the state of the social sciences to anatomy before Harvey. Without immodesty, he might have drawn a moral from the generation which followed Harvey's work. The most conspicuous example of healthy growth in contemporary social research is the study of population on the lines initiated by three men whose names appear on the list of original fellows of the Royal Society. The pioneers of British demography were Graunt, Sir William Petty and Halley. Graunt figures as the "ingenious author of the Mortality Bills" in the first history of the Society by Sprat, Lord Bishop of Rochester. Halley published the first life table, in the *Philosophical Transactions* of 1693. Since the first meetings of the 'Invisible College' were in Petty's rooms, the author of the "Politicall Arithmetick" shares with the "father of chemistry and the uncle of the Earl of Cork" the honour of being one of the first parents of the Society. Thus quantitative and realistic social inquiries shared in the efflorescence which followed Harvey's death.

After the lapse of little more than a century, Bentham exclaimed, "compare the state of chemistry then and now!" He might well do so. Chemistry in Bentham's time had just thrown off the self-evident principles involved in phlogistonism, and demography had taken up the self-evident principles of the gloomy parson. In his own day, Bentham's appeal for the reunion of naturalistic and humanistic inquiry made no ripple on the complacency of classical humanism in the established seats of learning, where the teaching of natural science prompted Babbage, Lucasian professor in the Newtonian succession, to write "The Decline of Science in England". No twentieth-century Babbage has appeared to compose a new "Economy of Manufactures".

Still, there are new signs of uneasiness about humanistic studies, and researches on population have become the focus of a new *rapprochement* between natural science and social studies. As in the times of Graunt, Halley and Petty, the new school of research draws its personnel from workers trained in the former. Revival of interest in population problems in Britain was initiated by the influence of two men. Sir William Beveridge graduated in astronomy: Carr-Saunders, his successor at the London School, was a professional biologist at an earlier stage in his career. The most challenging investigation of the British prospect has been that of Dr. Enid Charles in the Department of Social Biology of the School.

Such reflections might well justify the hope that the new Institute will welcome advice from men of science and recruit its personnel from scientific workers. So far, we have had no indication that it will. This is the more curious in view of the place which Sir Josiah Stamp occupies as its new president In his British Association address, Sir Josiah urged, and rightly urged, that the "Impact of Science on Society" is the central theme of fruitful inquiry into current affairs. To his recently published volume of addresses he has added an appendix on research finance prepared for him by one of his scientific friends. None should know better the relevance of naturalistic knowledge to contemporary social research, and none should know better the value of closer co-operation between those engaged in realistic social inquiries and those who have a wide experience of the financial needs of large-scale research work. If the new Institute is going to tackle the fundamental problems arising from the way in which expanding technical resources react upon, and are used by, existing social institutions, the existing departments of economics in our universities will not supply the recruits which it needs most. If it is not going to tackle these problems, it will do little to reinstate confidence in social research under academic auspices.

Elementary Geometrical Optics

(1) Practical Physics for Inter. B.Sc. Students
By Dr. H. M. Browning and L. Starbuck. Pp. x + 146. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1936.) 3*s*. 6*d*. net.

By Prof. John A. Eldridge. Pp. x + 616. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1937.) 18*s*. 6*d*. net.

IN 1934 a committee of the Physical Society published a valuable report on the teaching of geometrical optics. The committee made a unanimous recommendation with regard to the convention to be observed for the sign of the power of an optical system. This convention is universal among opticians, and may be expressed briefly by saying that a positive lens tends to converge and a negative lens to diverge the light. A more difficult problem to solve is that of obtaining agreement as to the sign conventions to be adopted when discussing the relations between object and image. Two alternative methods were advocated, which may be called the Cartesian and the non-Cartesian systems.

The committee expressed the opinion that the preference for one or other of these systems in elementary teaching should rest on experience with both in the schools. It is accordingly a matter of interest, and indeed of considerable importance, to determine to what extent older conventions have been discarded and which of the proposed alternatives seems likely to be adopted. Most of the school text-books, and those used in junior university courses, formerly agreed in assigning a negative focal length to a converging thin lens. Distances on one side of the lens were considered positive, those on the other side negative, and distances were considered positive when measured in a direction towards the source of light.

(1) This 'old' convention, which we shall call convention *A*, is still employed in the recently published "Practical Physics" for Intermediate Science students written by Browning and Starbuck. (2) In the second (revised) edition of his "Textbook of Light", Mr. Middleton, of Latymer Upper School, has done a useful piece of work

by showing side by side the results of using three sign conventions. He retains the 'old' or A convention, and also introduces the new sign conventions recommended in the report of the Physical Society with the view of giving a positive focal length to a converging thin lens. The convention which he calls B differs from A in that distances are counted positive when measured from the pole in the same direction as that in which the incident light travels. Thus A corresponds to Group I, Case 2, of the report, and B to Group I, Case 1. Both of these conventions are based on the Cartesian framework. The third convention, which Mr. Middleton calls C, corresponds to Group II, Case 1, of the report. "Distances are measured from the mirror or lens and are counted positive if actually traversed by the light, but negative if the light only appears to travel in that direction. Thus for a real image v is positive, and for a virtual image v is negative. Also concave mirrors and convex lenses have positive focal lengths, while convex mirrors and concave lenses have negative focal lengths "

In the report the last method of dealing with optical problems is described as a "non-Cartesian" system. In view of the fact that stress is laid on a clear distinction between "object space" and "image space", I suggest that this may be called a "spatial" system, and convention C (that is Group II, Case 1) the "spatial" convention. It should, however, be noted that it is possible to develop the relations between object and image without express reference to these "spaces" (which may confuse a beginner), and this is the plan adopted in the above and some other books.

As illustrating Mr. Middleton's presentation we may quote his equations for a thin lens. It is, of course, obvious to the teacher that equations involving only reciprocals of a distance must have the same form under convention A as under convention B, since the sign of each distance has been reversed.

Convention *A*

$$\frac{1}{v}-\frac{1}{u}=\frac{1}{f}$$

$$1 = (\mu-1)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

Convention *B*

$$\frac{1}{v}-\frac{1}{u}=\frac{1}{f}$$

$$\frac{1}{f}=(\mu-1)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

Convention *C*

$$\frac{1}{v}+\frac{1}{u}=\frac{1}{f}$$

$$\frac{1}{f}=(\mu-1)\left(\frac{1}{r_1}+\frac{1}{r_2}\right)$$

For a spherical mirror all three conventions lead to the same general formula:

$$\frac{1}{v}+\frac{1}{u}=\frac{2}{r}=\frac{1}{f}.$$

The author emphasizes the fact that it is only necessary for the student to know, and understand, one of these conventions. The value of the comparisons will be appreciated rather by the teacher, who wishes to make his choice between the conventions, than by the beginner, who may feel some alarm at their abundance.

(3) In the third edition of "Light", by Mr. Saunders, of Uppingham School, the sign convention used in geometrical optics "conforms to the convention used in algebraic graphs" and makes a convex lens have a positive focal length. The diagrams are drawn with the light moving from left to right across the paper (Convention B). Incidentally, mention may be made of the very interesting historical references in this book, and also of the chart of electromagnetic waves included by permission of the Royal Society.

(4) Mr. Noakes, of Giggleswick School, has written a "Textbook of Light" for the use of sixth-form students who are specializing in science. He has adopted many of the suggestions of the 1934 report, and in particular uses one of the two alternatives there recommended (Convention C). All real distances are reckoned positive, and all virtual distances negative; the focal length of a converging lens is thus positive. His conclusion is: "My experience with this sign convention has so far been that pupils consider it much less artificial than the Cartesian system, employed in most older text-books, and that the average careful worker makes fewer slips".

In view of the opinion of the committee of the Physical Society that actual experience in schools should be a deciding factor between the two alternatives, Cartesian or spatial, this conclusion is of special importance, and it is very desirable that it should be confirmed by other teachers. It agrees with the remarks of Mr. Vinycomb in the Physical Society discussion (p. 77), who found that elementary students were more successful with conventions of sign depending upon the real or virtual character of the object and image.

Why, it may be asked, should fewer mistakes occur when the "spatial" convention is employed by beginners? One reason is that the distinction between the object space and the image space itself takes care, to a large extent, of the question of sign. This is shown by the fact that the formula $\frac{1}{v}+\frac{1}{u}=\frac{1}{f}$ applies to both mirrors and lenses. With the older (Cartesian) conventions a separate formula $\frac{1}{v}-\frac{1}{u}=\frac{1}{f}$ is required for lenses, and it is necessary for the pupil to remember which formula applies to the lens and also to associate the letter u with the object and v with the image. There are thus two distinct possibilities of confusion in the mind of the beginner.

(5) In the fifth edition of Stead's "Elementary Physics", in which stress is laid on medical applications, the author states that he has adopted a new sign convention for lenses partly because of the support for the proposals of the committee of the Physical Society given by many members of the Science Masters' Association. "I confess that I have done this with some reluctance, as I am not altogether convinced of the wisdom of the change, so far as elementary students are concerned, but it has at least the advantage of giving the same standard formula for lenses and mirrors, and of bringing the signs of lens powers into line with those used by opticians and ophthalmic surgeons". The convention as to signs for thin lenses is expressed as follows (§ 232): "All distances are measured from the centre of the lens *C*. The distance from *C* of a real object or image is counted as positive, and the distance of a virtual object or image is negative. Since a convex lens has a real focus its focal length is positive; similarly the focal length of a concave lens is negative." The convention is essentially the same as that adopted by the author for mirrors (§ 215).

The curvature method advocated several years ago by Dr. C. V. Drysdale is both interesting and instructive, but my experience in teaching first-year university students has been that lack of time prevents more than a very brief reference to this method of treatment. It seems probable that schoolboys beginning the subject of light will think more easily in distances than in curvatures, and more advanced students can take up the curvature idea at a later stage after having had a taste of wave theory.

A stimulating, and in places provocative, book on "Physics for Medical Students" has been written by Mr. W. H. White, "one who has had time to learn how". On page 416 he writes: "The study of thin lenses is commonly carried on under the shadow of an algebraic convention as to 'sign' which makes distances measured opposite ways from the lens opposite in sign. That sounds simple and rational enough, and so it is from the point of view of geometry, but it has not the slightest physical basis". He aims at giving a physical meaning to + and − by picturing plane waves of sunlight falling on a lens (burning glass) and becoming curved to circular ripples which all close in on the burning focus *F*. Translated into 'rays', parallel rays become convergent radii which all pass through *F*. A concave lens has the effect of making parallel rays divergent. This leads up to the explanation of the focal power of a lens.

(6) It is interesting to find that in a new American book, "College Physics" by Prof. John A. Eldridge of the University of Iowa, the wave method is applied for finding the focal length of a double convex lens, and the rule of signs employed for mirrors and lenses corresponds fairly closely with convention *C*. This is a useful book for a student with only a general interest in physics, and yet should give a solid foundation for those intending to take a professional training at a later stage.

Which convention ought to be adopted?

Apart from the fact that such a phrase as 'Cartesian co-ordinate system' is alarming to a beginner, too rigid an adherence to a Cartesian framework may defeat its own aims, as, for example, when two students are working on opposite sides of a laboratory table, one having the source of light on the right, the other on the left!

In favour of convention *A*, as against convention *B*, it may be argued that this makes the co-ordinate u of the object, the first quantity to be dealt with, positive. The more negative quantities there are in u,v,f, the greater is the chance of error. In the greater number of problems set the object is given and either v or f is required. There is an advantage, therefore, in having u positive. Again, in the simple case of a real image formed by a concave spherical mirror (usually one of the first to be treated) the distances u, v, f are all positive according to convention *A*, but with convention *B* they are all negative.

If we consider the choice of our convention from the point of view of the teacher of elementary students, it would seem that convention *C* is to be preferred to convention *B*, in so far as there is less risk of mistakes in sign. The spatial convention does, however, strictly involve distinction between real and virtual spaces and so may cause confusion. The 'existence' of virtual images does present a difficulty to some minds, and there is the additional trouble that the student does not always know whether the image is going to be virtual or not. The difficulty is even greater to such minds when problems involving a 'virtual object' come to be dealt with.

Under present conditions, with so many methods of treatment in use, the outlook for a student or a science master who is transferred from one school to another is not an inviting one, and the task of an examiner who has to mark questions in optics answered by candidates from different schools becomes well-nigh impossible. It is to be hoped that teachers of physics will speedily reach agreement as to the convention to be used by elementary students. Personally I began the examination of this question with a prejudice, shared by many others, in favour of the 'old' convention *A*, but if we are compelled to follow the opticians' terminology the present survey points towards the adoption of *C*, the "spatial" convention, rather than *B*, the "Cartesian" convention.

H. S. ALLEN.

The Experimental Production of Mutations

Experimentelle Mutationsforschung in der Vererbungslehre

Beeinflussung der Erbanlagen durch Strahlung und andere Faktoren. Von N. W. Timoféeff-Ressovsky. (Wissenschaftliche Forschungsberichte: Naturwissenschaftliche Reihe, herausgegeben von Dr. Raphael Ed. Liesegang, Band 42.) Pp. x + 181 + 6 plates. (Dresden und Leipzig: Theodor Steinkopff, 1937.) 15 gold marks.

THE last decade has seen remarkable activity in the experimental production of mutations in animals and plants, chiefly through the agency of X-rays but also by the application of various other radiations, as well as by chemicals and by temperature effects. When the range of dosage was determined within which the cell and particularly the chromosomes could be bombarded without an immediate lethal effect, the way was open for unlimited experimentation in the production of new genetic types through a direct effect on the germ-plasm.

So early as 1907–8, experiments were published showing the effects of X-ray treatment on the sperm of toads and rabbits, and Gager obtained evidence of mutations resulting in plants from the action of X-rays and radium. But success on a large scale first came from the work of Muller on *Drosophila* in 1927. The subsequent literature of the subject has become extensive, as indicated by the 27 pages of bibliography in the present volume. This experimental work has contributed much to the development of the conception of the gene, although, of course, natural mutations are of at least equal value in this respect.

Timoféeff-Ressovsky has contributed to all aspects of this work during the past ten years, and he has shown special interest in the nature of the gene from a physico-chemical point of view. It is therefore natural that he should have produced a book on this subject which is of great interest and analytical value. The work contains ten chapters. After four chapters of an introductory and general character, three are devoted to analysis of the processes by which mutations are produced by short wave-length radiation. Here *Drosophila* naturally looms large as having been most intensively studied, but the work of Stadler on cereals, Stubbe on *Antirrhinum*, and many other results are also considered.

Another chapter, on the effects of temperature, chemical treatment and other factors, is followed by one on gene structure, in which step-allelomorphism and the 'position-effect' are discussed, and the process of mutation is subjected to biophysical analysis. Evidence is produced for the conclusion that some mutations are the result of a very small rearrangement of the genes (position-effect), similar to inversions and translocations but on a smaller scale.

A final chapter considers the applications of the results to theoretical genetics, the chromosome theory and the phenomena of somatic induction, as well as the practical applications to experimental breeding and to man. The author may be assured that his book will be of much service not only to those engaged in this experimental field but also to all who are interested in modern genetical theory.

R. Ruggles Gates.

Tables for Air Navigation

The Air Almanac

Prepared by H.M. Nautical Almanac Office on behalf of the Air Ministry. (Air Publication 1602.) Pp. 16. 2*s*. 6*d*. net. Ephemeral Sheets for 1937, October 1 to December 31. (Air Publication 1602A.) Pp. 92. 2*s*. 6*d*. net. (London: H.M. Stationery Office, 1937.)

THE growing importance of astronomical observation in air navigation, as a result of the increasing range of aircraft, is reflected by the recent publication of an "Air Almanac", specially designed to meet the requirements of air navigation. The "Abridged Nautical Almanac" already gives to the surface navigator the astronomical data required to an accuracy of 0·1′ or 0·2′, but involves certain interpolations and conversions that can be avoided in an almanac catering only for one tenth of this accuracy, which is that appropriate to the conditions of observation with a bubble sextant in aircraft. This lower degree of accuracy gives the air navigator his position with all the precision that he needs. His prime requirement is rapidity in the working up of a sight.

The most interesting feature of the "Air Almanac" from this point of view is the tabulation of the Greenwich hour angle in arc, instead of the right ascension in time, thus giving directly the quantity that the navigator desires, without subsequent conversion. This method of tabulation normally involves large differences and heavy interpolations; but the small intervals of tabulation adopted, namely, one hour for the sun and moon, six hours for the planets and ten minutes for the sidereal time or Greenwich hour angle of the First Point of Aries, have made possible considerable simplification.

The "Air Almanac" has been designed to give all essential information in light, compact and easily readable form, with page references and interpolations reduced to a minimum. This has been achieved by issuing the "Almanac" in two parts, one of which consists of a stout permanent binding containing all the permanent data and tables, together with short explanations and illustrations; and the other consisting of loose sheets, each of which contains all the necessary ephemeral data for two days for the sun, moon, Venus, Mars, Jupiter, Saturn and fifty bright stars. The ephemeral sheets are punched for easy attachment to a loose hinge in the permanent cover. When one of these sheets is in position, the necessary astronomical data together with suitable interpolation tables are available in the space of a few pages. This reduces the bulk and greatly facilitates reference. Thus, though the ephemeral sheets for one year considerably exceed the "Abridged Nautical Almanac" in bulk, in consequence of the method in which the data are presented it is never necessary for the air navigator to carry more than a few sheets at any time.

Apart from the primary use for air navigation, it is certain that considerable interest will be expressed in the possibility of using the "Air Almanac" for surface navigation and also for incorporating afterwards similar ideas in the "Abridged Nautical Almanac". For the traveller in remote parts, a small bubble sextant in conjunction with the "Air Almanac" will suffice to fix his position with the accuracy that he usually needs.

The "Air Almanac" has been produced by H.M. Nautical Almanac Office to the general requirements of the Air Ministry, by agreement with the Admiralty. It is published by H.M. Stationery Office under the Code Air Publication 1602 for the permanent portion and 1602A for the ephemeral sheets. The first issue of the ephemeral sheets was for the period October 1–December 31, 1937. These sheets are to be issued in advance at first quarterly, later at intervals of six months, and finally annually.

Theory of Statistics

An Introduction to the Theory of Statistics
By G. Udny Yule and M. G. Kendall. Eleventh edition, revised throughout and re-set. (Griffin's Scientific Text-Books.) Pp. xiii + 570. (London: Charles Griffin and Co., Ltd., 1937.) 21*s*. net.

MR. UDNY YULE'S "Introduction" was the first book on statistics that came into my hands. This was about 1916. I liked it then and learned a lot from it. I like it even more now in its eleventh edition, when it appears in a revised and supplemented form. In fact, in my opinion, this is the best book on the theory of statistics that was ever written. We may regret only that it is an elementary introduction to the theory of statistics and not the theory itself. This still remains to be written.

The authors make a distinction between books on the 'theory of statistics' and those on 'statistical method'. They do not discuss this distinction in the text but emphasize its importance in classifying the existing literature (p. 496). The words "Theory" or "An Introduction to the Theory", etc., suggest a system of conceptions and theorems properly defined and proved. Some of the results thus obtained may be directly used for applications; but the main purpose of the whole is to broaden the horizon of the reader and to make him understand the purpose and the real meaning of 'recipes' that he may find in books on "Methods". It is true that the classification of the existing literature from this point of view could not be objectively distinct, since every book "on Methods" does give, or attempts to give, some explanation of what the reader is recommended to calculate. Whether these attempts are sufficient in any particular case is a matter of opinion, and it is possible that the classification as offered by Yule and Kendall will not be generally accepted. But the idea of the distinction itself and also the desirability of more books on the 'theory' seem to be important.

However difficult it is at present to write a book on the theory of statistics, it is still more difficult to produce an elementary "Introduction to . . ." "The Theory" implies a unicity of the basic ideas, in fact a system, as we have systems of geometries, Euclidean, Lobatchevsky-Boliay'an and Riemannian. Such a unified system of statistics, including all the recent advances, does not exist yet, and the writer on the subject must first produce one and then describe it in an intelligible way. These are the difficulties in writing a "Theory".

When writing "An Introduction", these difficulties are somewhat diminished by the fact that the system to be produced and described need not be so broad and may omit the more recent results. But there are other specific difficulties, to present the system without elaborate tools of higher analysis.

In this task the authors have succeeded admirably. They have produced a system of conceptions and their consequences, reaching as far as some of the quite modern tests of significance. They insist on definitions and are careful to use the words in their defined meaning. They even produce lists of defined terms used by other writers. When leaving out some results which are too difficult to be produced or omitting some proofs, they do it in a way which permits the reader to distinguish between what he knows and what he does not. This may seem only conventional praise. To understand its importance the reader may wish to consult some of the popular books on the "Methods" where, instead of properly ordered definitions and deductions, he will frequently find a sort of mystic gospel full of mysterious terms and impressive formulæ.

The new edition of the "Introduction" differs considerably from the preceding ones. The difference consists mainly in numerous smaller additions disseminated abundantly throughout the book and of several new large chapters. As stated in the preface, one of them, on interpolation and graduation, is due to Mr. Udny Yule himself. The others, on sampling, including an introductory chapter on small samples, on moments and measures of skewness and kurtosis and on the method of least squares have been written by Mr. Kendall. Probably owing to a close collaboration between the two authors, their respective contributions fit very well together and form a harmonic whole.

A noteworthy innovation in the book is a set of the most important numerical tables and a diagram (pp. 531–541) which are needed in any serious statistical work.

As in former editions, there are numerous examples discussed in the text and also "exercises". There are various problems attached to every chapter, which the student will find useful. The solutions of these problems are given in a special section at the end of the book.

The list of references given in the book contains 680 entries. It goes as far as 1932 and is not considered by the authors as complete. It seems, however, a pity that while quoting twelve books on probability, the authors do not refer to the work of the very important present-day French School. There is no reference to E. Borel's "Traité du Calcul des Probabilités", composed of about a dozen volumes, contributed either by Borel himself or by his various collaborators. There is no reference either to the important book by Paul Lévy.

There are a few minor points on which I am inclined to disagree with the authors. Of these it may be perhaps worth while to mention the definition of the word statistics. The authors write (p. 3), "By Statistics we mean quantitative data affected to a marked extent by a multiplicity of causes. By Statistical Methods we mean methods specially adapted to the elucidation of quantitative data affected by a multiplicity of causes. By Theory of Statistics or, more briefly, Statistics, we mean the exposition of statistical methods".

Naturally every author may choose the definition he likes, but it seems to me that the whole book under review has been written as if the authors had in mind another definition of statistics, that suggested by the German term *Kollektivmasslehre*. In fact, whatever they discuss is either the properties of some *Kollektivmass* (= collective character ?), such as the frequency distribution, measures of contingency, that of skewness, etc., or the means by which such a *Kollektivmass* of an inaccessible universe may be estimated from the sample available. The question of the "multiplicity of causes" seems to arise only before and after a statistical inquiry in the strict sense of the phrase.

Instances of this are given in a very interesting chapter (xv) on illustrations and practical methods. Having to solve some particular social (or any other, agricultural, physical, etc.) problem, we start by discussing the multiplicity of causes and, as it were, translate the problem into statistical terms. Then follows the statistical work proper and, when it is completed, we return again to draw conclusions concerning the causes. But these two phases of the inquiry, the first and the last, seem to belong rather to sociology, economics, agriculture or whatever may be the branch of science to which statistical methods are applied, but not to the statistics itself.

We may conclude by expressing the hope that the book in its new form will have a very wide circulation.

J. NEYMAN.

Gold Deposits of the World:
with a Section on Prospecting. By Prof. William Harvey Emmons. Pp. vii+562. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 36*s*.

PROF. EMMONS'S name is sufficient guarantee that a book from him merits serious consideration. In this work, an "Introduction", which is rather fuller than such chapters are wont to be, will be found helpful to many students and to some who have passed the student stage, especially in the elucidation of bathyliths and their relation to gold deposition. Excluding this and the index, which occupies eighteen pages, half the book is taken up in descriptions of American gold occurrences, and the balance is left for the remainder of the world. It is this latter half that is open. to criticism. For so dominant a producer as the Rand, more up-to-date figures might have been given for individual mines as regards values, widths, working costs and tonnage. For example, one diagram is based on assays made in 1913: the recent developments in which West Witwatersrand Areas, Ltd. has so prominently figured are almost passed over, and the plan of the Rand printed on p. 421 is too small and confused to be of much value. The absence of recent data is noticeable throughout this part of the book; thus it is stated that, "No production is reported for Sierra Leone", whereas the Colonial Report for 1935 gives "32,947 ozs. (crude)"; that in Tanganyika Territory the area north-east of Mwanza is unmapped, whereas excellent geological maps were published a few years ago.

In dealing with America, Prof. Emmons is on surer ground and writes fully with an authoritative hand. The descriptions of the mines are backed by an immense series of facts and figures, and throughout, with rare exceptions, the maps and diagrams, of necessity small, are admirable and sufficiently clear. Plentiful references to earlier works are given. The chapter on "Prospecting" contains some useful notes on controlling structures and references to examples in the text, but the author has not extended this part of his subject to descriptions or discussions of mechanical or geophysical methods. Despite the relatively small defects mentioned, this comprehensive volume will undoubtedly prove of great value to all interested in the geological and economic aspects of its subject. J. P.

The Fauna of British India, including Ceylon and Burma
Edited by Lt.-Col. R. B. S. Sewell. (Published under the authority of the Secretary of State for India in Council.) Protozoa: Ciliophora. By Dr. B. L. Bhatia. Pp. xxii+493+12 plates. (London: Taylor and Francis, 1936.) 30*s*.

THE present volume, one of the latest in the series on "The Fauna of British India, including Ceylon and Burma", though devoted only to those members of the sub-phylum Ciliophora, or ciliate infusoria, which have been recorded from the countries named, will be of more general interest to zoologists, in view of the cosmopolitan distribution of the majority of these Protozoa, and also because there is no recent publication in the English language dealing with this group in a comprehensive manner. This work represents a systematic survey of the Ciliophora, of which 310 species, including several new ones, are briefly described. The classification of the group adopted by Dr. Bhatia is up to date. Keys are provided for the identification of families (including those hitherto not recorded from India), genera and species. A useful "Systematic Index" combines a résumé with a classified list of the organisms dealt with. The ciliate species are also arranged in groups, according to their geographical distribution, while cross-reference lists are given for the parasitic forms and their hosts. A brief description is given of the general morphology of the Ciliophora and of the methods employed in their study.

There is an exhaustive bibliography occupying 46 pages and an alphabetical list of the ciliates referred to in the book, as well as a map of the Indian Empire. The volume is abundantly illustrated by text-figures and twelve plates. The latter represent the Ophryoscolecidæ found in the Indian ox and are reproduced from Kofoid and MacLennan's studies on these ciliates. It is somewhat surprising to find that, in a book devoted to the entire sub-phylum Ciliophora, all the plates are allocated to the representatives of a single family. C. A. HOARE.

The Scenery of England:
a Study of Harmonious Grouping in Town and Country. By Dr. Vaughan Cornish. Second edition. Pp. xvi+144+15 plates. (London: Alexander Maclehose and Co., 1937.) 6*s*. net.

DR. VAUGHAN CORNISH is an eminent example of the type of observer who not only appreciates the best characteristics of the works of Nature and of man but also interprets them with scientific understanding. The first edition of his charming little book was noticed in NATURE of November 19, 1932 (130, 760); and we are glad to direct attention to this new issue, which contains an appendix by Mr. H. G. Griffin, secretary of the Council for the Preservation of Rural England, on the aims and objects of the Council. The book has been enlarged and revised, and ten of the fifteen full-page plates in it are entirely new. The picture of the tidal bore of the Trent at Knaith, above Gainsborough, a subject to which Dr. Cornish has given particular attention, is remarkably fine. Every intelligent lover of 'open-air' scenes in town or country will find the book a source of real pleasure.

Earth-Lore:
Geology without Jargon. By Prof. S. J. Shand. Second edition, revised and enlarged. Pp. viii+144+16 plates. (London: Thomas Murby and Co., 1937.) 3*s*. 6*d*. net.

"GEOLOGY WITHOUT JARGON" aptly describes Prof. Shand's entertaining and informative little book. The second edition has been improved by the addition of a number of plates and other illustrations; and there is a new chapter on Atlantis and other "Lost Continents".

Exploration of the Electric Field in Clouds

THAT there is electricity in the clouds has been realized since 1755, when sparks were drawn from the insulated rod set up by D'Alibard and from Franklin's kite, but the problem how to determine with certainty where the electrification was situated had been left unsolved until a method was suggested by Sir George Simpson three years ago and developed at Kew Observatory by Mr. F. J. Scrase.

There has, it is true, been much speculation on the subject, speculation depending on the records of potential near the ground and especially on measurements of the change of gradient produced by lightning flashes. The problem, given the distribution of electricity, deduce the strength of the electric force at a certain point, is easily solved; but the converse problem, given the electric force at a single point, find the distribution, is not soluble. Even if we knew the electric force at every point on the ground, we could not determine the distribution of electricity in the clouds and in the air below the clouds. That is why the interpretation placed upon his records by an investigator has not necessarily been acceptable to his colleagues, and there has been much room for controversy. To gain more intimate knowledge of the state of things in the clouds it was necessary to send up into the clouds apparatus suitable for the purpose. I do not think that this was fully appreciated by anyone until we had tried at Kew Observatory to learn the meaning of the potential gradient records obtained in disturbed weather and had to admit that we were baffled by the ambiguities.

Electrometers had already been sent up in sounding balloons. In 1926 and 1927, Idrac measured the potential gradient in fine weather by means of a valve electrometer and a milliammeter, the indications of which were photographed, but none of his soundings was made through big clouds, and after his untimely death the investigation, which had been carried out at Trappes, was discontinued. For the work at Kew it was anticipated that numerous instruments would be required and they had to be as simple as possible. Sir George Simpson pointed out that it was more important to find the sign of the potential gradient than to measure it, and suggested the use of pole-finding paper. That idea was speedily developed, and the first alti-electrograph was sent up a few weeks later. This rapid advance was possible because Mr. L. H. G. Dines had already designed for Sir George Simpson a meteorograph which was intended to detect the presence of vigorous vertical air currents in the clouds. It was only necessary to put on the same spindle as the disk on which the pressure was recorded another disk carrying a piece of prepared paper. During the next two years, some seventy alti-electrographs were sent up from the Observatory.

During an ascent, the electrograph is in series with a pendant wire about twenty metres long, from the end of which there is point discharge whenever the electric field is strong. Two pin-points make contact with paper impregnated with a solution containing potassium ferrocyanide, and a blue trace is made by one pin or the other as the potential gradient is positive or negative. It was soon found that the thickness of the trace depended on the strength of the gradient, so the records are to a certain extent quantitative as well as qualitative. Most of the ascents were made during thunderstorms or thundery showers, the voltameter not being sensitive to the potential gradients in the clouds which yield moderate rain. To diminish the risk of the alti-electrograph being carried out to sea, a Baker release was used so that the apparatus would be carried down by a parachute from a height of a few kilometres.

The records have been analysed by Sir George Simpson and Mr. Scrase, and their conclusions are set out in a paper recently published by the Royal Society (*Proc. Roy. Soc.*, A, **161**, 309–352, August 1937). Some of the balloons sent up were not recovered, and in many cases the electric field was not strong enough to be recorded; but for the period up to the end of 1936 there were thirty-one records available for discussion. Most of the soundings had reached heights of about 7 km. as was intended, but in two cases the balloons had ascended to much greater heights, 15 km. and 17 km., and recorded strong gradients in the stratosphere.

At first glance there is much diversity in the records, but the analysis has yielded a number of valuable generalizations. The first is that in practically every ascent there is a change in the sign of the potential gradient. This is an indication that the balloon passed from below to above a region of concentrated charge. The second generalization is that the location of the charges is related to the temperature of the cloud. These two conclusions are illustrated in a very instructive diagram (Fig. 1).

In this diagram the ascents were arranged in order according to the height at which the

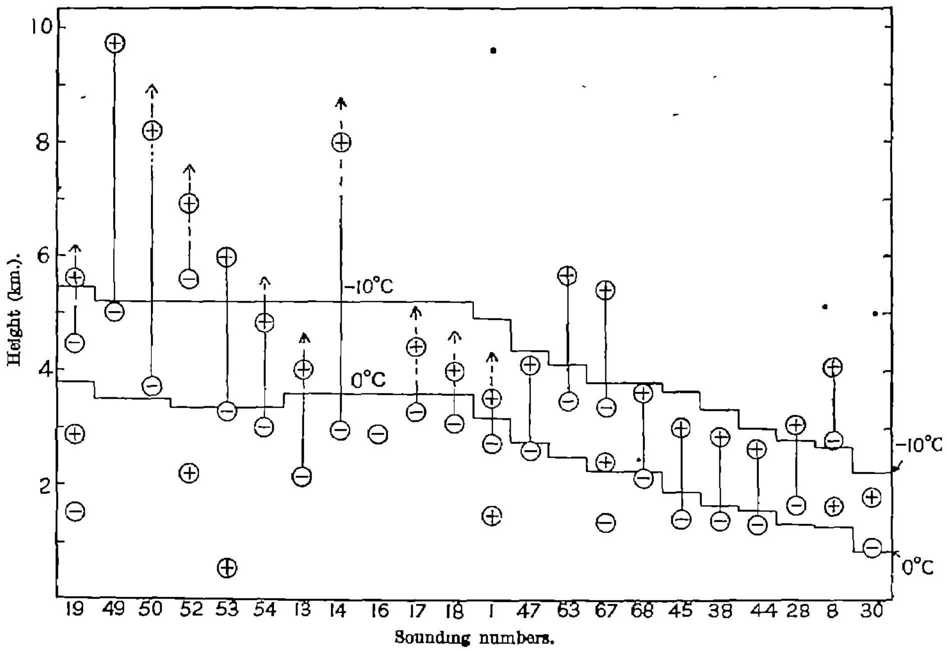

Fig. 1.

HEIGHT OF CENTRES OF RAIN ELECTRICAL CHARGES. FROM *Proc. Roy. Soc.*, A, 161, 309–352 (1937).

temperature (calculated by assigning reasonable values to the lapse-rate below and in the cloud) was −10° C.

It will be seen that in every case there was evidence for a positive charge near the greatest height reached by the sounding, and, moreover, this positive charge was always in a region where the temperature was below the freezing point. Clearly, positive electrification is developed in the part of the cloud where there is snow and possibly hail. The complementary negative charge is generally near the bottom of the cloud. There are, however, a few cases in which there is a concentration of positive electricity at a low level, an indication that there is a second process at work in the part of the cloud where the snow has melted into raindrops.

Hitherto, in most discussions of the possible ways of generating electricity in the clouds, attention has been concentrated on the behaviour of raindrops, in spite of the fact that the thunder-cloud is usually capped by false cirrus and in spite of the general acceptance in recent years of the doctrine, strongly advocated by Bergeron, that rain is nearly always melted snow. The discovery that electrification is produced in the region in which there is snow recalls, however, the early theory of thunderstorms developed by L. Sohncke, of Munich, in a pamphlet published at Jena in 1885 (cf. *Met. Z.*, 5, 413–425; 1888). Sohncke maintained that the electrification was produced by friction between ice and water, the ice acquiring a positive charge, the water a negative charge. If this theory had been correct, the negative charge on the cloud particles would have been carried upwards by convection currents and the snow would have carried a positive charge downwards. Actually the positive charge is found at the top of the cloud, so Sohncke's theory cannot be valid.

Simpson and Scrase remark that when there is driving snow near the ground, a strong positive gradient is developed. This was demonstrated by Simpson in the Antarctic and confirmed by Sverdrup during the voyage of the *Maud* in the Arctic

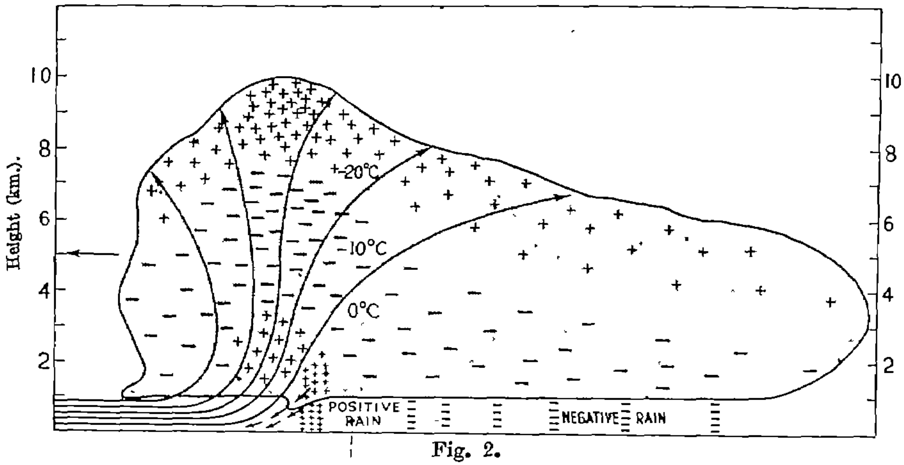

Fig. 2.

GENERALIZED DIAGRAM SHOWING AIR CURRENTS AND DISTRIBUTION OF ELECTRICITY IN A TYPICAL HEAT THUNDERSTORM. FROM *Proc. Roy. Soc.* A, 161, 309–352 (1937).

Ocean. It is likely that when snow particles collide, the particles acquire a negative charge, whilst a positive charge is given to the air. The snow falls to the ground and a positive space charge remains in the air and may extend to a considerable height. The process is analogous to what happens in a sandstorm, though the sign of the electrification is reversed. Thus it is to be expected that in the part of a cloud where there are snow particles in violent motion there will be electrification, that the snow will carry down a negative charge and that the air streaming upwards will take a positive charge to the top of the cloud, this charge being communicated rapidly to the cloud particles. It may be added that as the cloud-top is in a region where the conductivity is high, a strong current of positive electricity can flow upwards to the Heaviside layer, so providing (in accordance with Wilson's theory) for the air–earth current of fine weather.

There is some evidence that the regions in which positive electrification is produced low down in the clouds are those where the rain is heaviest, and Simpson and Scrase hold that the breaking-drop theory of the former is the explanation of this electrification. As the snow melts, it forms large drops, and if these are too large for stability they will break up. The rising current of air will carry a negative charge and the positively charged droplets fall or perhaps remain nearly stationary. The hypothesis that this process occurs only where the upward current is strong is embodied in Fig. 2.

Perhaps the most surprising result of the investigation is that no evidence is found for very strong fields in the clouds. The magnitude of the potential gradient is determined by a tentative formula which takes account of the width of the trace on the electrogram and also of the density of the air. It was found that when the gradient exceeded about 100 volts per centimetre, the trace was marked by sparking, but this occurred in only a few of the ascents. In 1925 Wilson put forward the hypothesis that, when a lightning flash is about to occur, the electric field just below a thundercloud is probably nearly 10,000 volts per centimetre, a hundred times the strength near the ground. The hypothesis seemed to be supported by estimates of the space charge produced by point discharge from trees and other objects. The soundings indicate, however, that generally there is little if any increase in the gradient as the cloud is approached. It may be that the estimates are systematically in error, and it is to be hoped that control measurements will be made by some more direct method.

One reason for suspecting such systematic error is that the estimated gradients imply that the charges in the clouds are comparatively small. If the gradients over two planes a kilometre apart are +100 v./cm. and −100 v./cm. respectively the charge is (by Coulomb's law) only 0·2 coulombs per cubic kilometre. This is insignificant compared with 20 coulombs, the quantity of electricity supposed to be discharged by a lightning flash. In what part of a cloud the lightning originates, and why it occurs, we have yet to discover.

The investigation is being continued at Kew and, although the ascents made during 1937 have not led to any striking new discoveries, it may be that in the course of time a record will be obtained which will provide the missing clue.

F. J. W. WHIPPLE.

Heat Production, Nutrition, and Growth in Man: Some New Views*

By Dr. E. P. Poulton

INDIRECT AND DIRECT CALORIMETRY

IN estimating the heat production of an individual, the oxygen intake and the carbon dioxide output are measured. After allowing for protein metabolism the oxygen intake is converted into calories of heat generated, by multiplying it with a factor which depends on the respiratory quotient (volume of carbon dioxide produced/volume of oxygen absorbed). These multiplying factors were calculated originally by Zuntz and Schumburg (1901), and are based upon: (*a*) the heats of combustion of carbohydrate and fat; (*b*) the chemical composition of carbohydrate and fat; and (*c*) the theory that when the respiratory quotient has the value unity carbohydrate alone is oxidized in the body and when the respiratory quotient has a value equal to 0·707 fat only is being oxidized, and at intermediate values of the respiratory quotient corresponding proportions of carbohydrate and fat are being oxidized. This method of calculating the heat produced by an individual is known as indirect calorimetry. The basal metabolism or basal metabolic rate of American authors or 'standard' metabolism of Krogh and Lindhard is at present defined as heat production in the morning before breakfast, fourteen to sixteen hours after the last meal of the previous day (the post-absorptive condition) with the subject lying at rest.

---

* Substance of the presidential address delivered to Section I (Physiology) of the British Association at Nottingham on September 2, revised and modified.

The heat output of man and animals, under basal conditions, has been measured directly in a calorimeter by Benedict and Carpenter, DuBois and his colleagues and Murlin and Lusk, and compared with the heat output calculated indirectly by means of the Zuntz-Schumburg figures from the oxygen intake and the carbon dioxide output, which were measured simultaneously. The results obtained have been held by their authors to justify the conclusion from average values that the agreement between the two methods was sufficiently satisfactory to give support to the theory of the 'variable combustion ratio' outlined above. However, this theory has not escaped criticism.

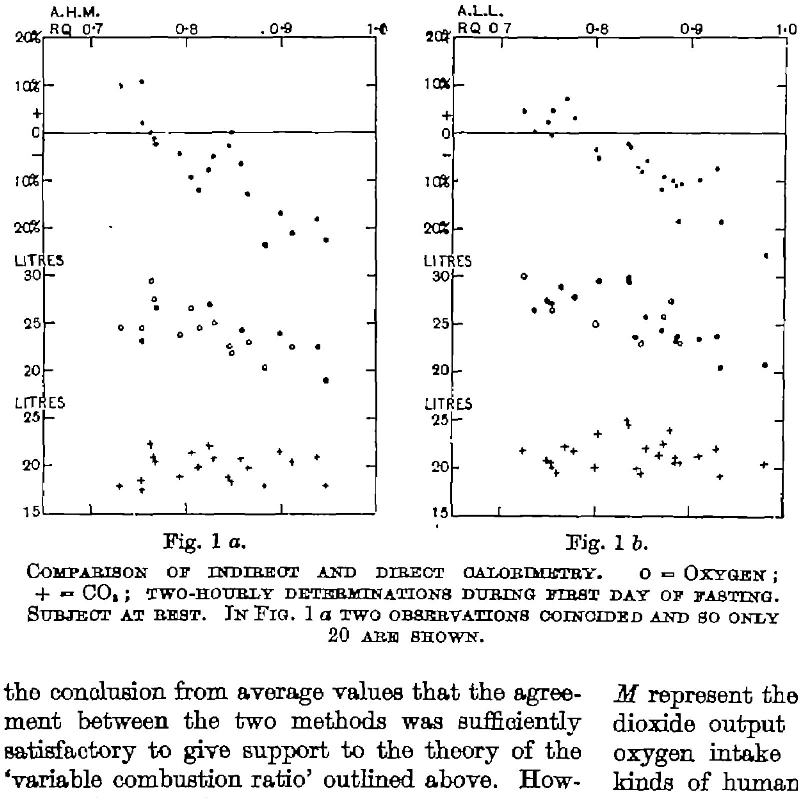

Fig. 1 *a*. Fig. 1 *b*.

COMPARISON OF INDIRECT AND DIRECT CALORIMETRY. o = OXYGEN; + = CO_2; TWO-HOURLY DETERMINATIONS DURING FIRST DAY OF FASTING. SUBJECT AT REST. IN FIG. 1 *a* TWO OBSERVATIONS COINCIDED AND SO ONLY 20 ARE SHOWN.

AN APPARENT ERROR IN INDIRECT CALORIMETRY

The most complete study of direct and indirect calorimetry in normal man under basal conditions is that made by Benedict and Carpenter. Using the data for two subjects, the theoretical heat from the oxygen intake and the respiratory quotient was calculated by the Zuntz-Schumburg method, and this heat (indirect heat) was compared with the heat actually measured by the calorimeter (direct heat). The difference between the indirect and direct heat was expressed as a percentage of the direct heat and related to the respiratory quotient by a graphic method. The result is shown in Figs. 1 *a* and 1 *b*. The horizontal line at zero in the top part of the diagrams represents the condition where the indirect and direct heats are identical; the ordinates represent the percentage differences between the indirect and direct heats. Satisfactory agreement between the heat calculated and the direct heat will depend on the percentage differences, indicated by the black dots, being evenly distributed above and below the horizontal zero line throughout the range of respiratory quotients. This is obviously not the case. The positions of the points suggest a systematic error; for the lower quotients the indirect heat is too high and for the higher quotients too low. DuBois' results tend to show the same thing, though not in such a striking way.

Another way of studying this question is to plot the carbon dioxide and oxygen independently against the heat (Fig. 2). The position of the points in the diagrams shows that there is a linear relation between the carbon dioxide and calories (correlation coefficient 0·950 ± 0·005) and between oxygen and calories (correlation coefficient 0·92 ± 0·008). The carbohydrate line is the relation of the carbon dioxide output and oxygen intake to the heat produced, when pure carbohydrate is burnt in a calorimeter; they were calculated from the value given by Lusk, namely, 5·047 Cal. per litre of oxygen and carbon dioxide. The lines *K* and *M* represent the relation of the heat to the carbon dioxide output on the left-hand side and to the oxygen intake on the right when two different kinds of human fat are burnt. These two fats, from liver and skeletal muscle analysed by Cathcart and Cuthbertson, were chosen because they represent extremes, and the lines of the other nine human fats analysed by them lie in between. Most of the carbon dioxide points lie between the theoretical carbohydrate and fat lines, which are widely spaced; but this is certainly not the case with the oxygen points, as the theoretical limits are much narrower. It is possible to look on the carbon dioxide as the product of combustion of a mixture of carbohydrate and fat, but, because the oxygen points lie for the most part outside the theoretical limits, the oxygen intake cannot, apparently, be entirely used up in combustion, but must in part be concerned in some kind of conversion.

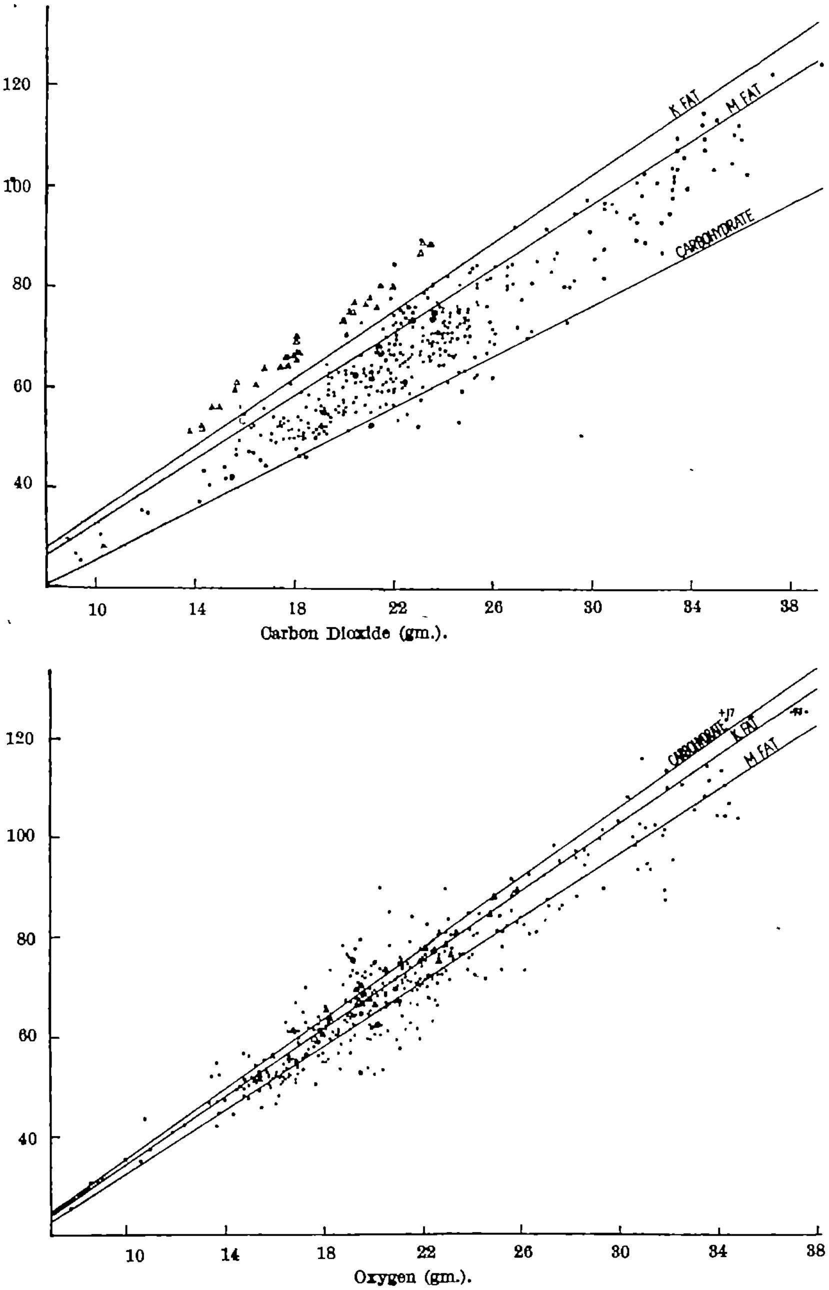

Fig. 2.

Comparison of indirect and direct calorimetry. DuBois' basal values (rectal temperatures not above 37·5° C.). Ordinates: Calories per hour; Abscissæ: Upper diagram—CO_2 gm. per hour; Lower diagram O_2 gm. per hour. ○ Two coincident values. Δ Alcohol control experiments.

However, work since Nottingham has exposed an error in these diagrams. In many of DuBois' results there was a considerable difference in the rectal temperature at the beginning and end of an experiment which was taken to imply a large physical liberation or storage of heat, depending on the temperature difference, the body weight and average specific heat of the body (0·83). But since the rectal temperature can only be a rough measure of the body temperature as a whole, it follows that when there are large differences between the eliminated heat (actually measured) and the direct calorimetry (the value after correction for heat physically liberated or stored), there must be considerable uncertainty about the results. It has been found on plotting heat against carbon dioxide, according to the quotient, that when the differences are greater or less than 10 per cent of the eliminated heat, many points fall a long way from the mean line; the eliminated heat has apparently been overcorrected. These uncertain results also form a high proportion of those outside the theoretical limits for oxygen and calories in Fig. 2, and they also seem to account for the similarity of the results of Benedict and DuBois, when the latter are calculated so as to form diagrams as in the upper part of Figs. 1 *a* and 1*b*. If all the uncertain results are eliminated the points in Fig. 2 lie nearer to the mean line, and now appear compatible with the theory of the variable combustion ratio. There is thus a discrepancy between the results of DuBois and those of Benedict, for the latter are incompatible with the theory.

[*To be continued.*]

Obituary Notices

Prof. J. B. Senderens

THE death on September 26 of Jean Baptiste Senderens, who was born in the village of Barbachen in the Hautes-Pyrénées in 1856, removes from our midst one of the most active workers in the field of contact catalysis.

Together with Sabatier in 1899, Senderens found that finely divided nickel could be employed as a catalyst for the hydrogenation of the vapours of a variety of organic substances, and with this discovery the intrusion of catalytic methods into technical organic chemistry may be said to have commenced. In fact, the first patent for the reduction of an organic substance by hydrogen in the presence of catalytic metals was granted to Senderens (*D.R.P.*, 139, 457, of July 26, 1901) for the production of aniline from nitrobenzene. It is possible that the achievements of Senderens would have left an even deeper imprint on modern chemical industry if he had not confined himself to reactions in the vapour phase and left the treatment of liquids, for example, modern fat hardening, coal and liquid tar hydrogenation, to others. Nevertheless, his technical contributions, especially in the field of fine chemicals, and in association with the firm of Poulenc Frères, are important and varied enough to leave industry permanently indebted to him.

One has only to glance at any text-book on contact catalysis to obtain some idea of the wide diversity of the applications that Senderens made of this new method of contact catalysis in the field of organic chemistry. The preparation of substances such as ketones from acids or of cyclohexane from benzene are indeed too numerous to mention. In respect to the theory of contact catalysis, Senderens was a protagonist of the view that intermediate compounds were formed between reactant and substrate—in more modern terminology, that chemisorption was a pre-requisite for chemical reaction. It may be noted that, in addition to the purely preparational character of his work, he made a number of very significant observations which must eventually find their place when we are in possession of the detailed mechanism of these surface reactions. Thus he noted that whilst benzene could be hydrogenated to cyclohexane, dehydrogenation could be effected at higher temperatures. Thus equlibrium can be obtained from both ends and permits of the accurate evaluation of the free energy changes involved in organic reactions. His work on this reaction renders Senderens a pioneer in what is now an important field of physical chemistry.

Again, Senderens observed that acetylene could be hydrogenated to ethane without the addition of hydrogen, the latter being supplied by simultaneous dehydrogenation of part of the acetylene; this reaction may be regarded as the prototype of important reactions involved in the oil industry, where the fundamental processes consist in the catalytic making and breaking of carbon-carbon and carbon-hydrogen bonds. He noted that nickel was a 'better' hydrogenating catalyst than copper; thus carbon dioxide can readily be converted to methane on the former but only to carbon monoxide on the latter metal; likewise amyl acetylene is converted to heptane on nickel but only to amyl ethylene on copper. Similarly, he pointed out that whilst an active nickel catalyst will hydrogenate both cresol and phenol, a nickel catalyst that had been employed for a long period in hydrogenating phenol was rendered inert for the cresol reaction. Here we are evidently dealing with cases of specificity, one of the most fascinating and mysterious features of contact catalysis.

Senderens' work was not confined to hydrogenation processes; he examined numerous cases of dehydrations, that of alcohol to ether or ethylene being the most important. Finally, we may mention that he initiated investigations in the much more difficult field of catalytic oxidations; for example, isoamyl alcohol to aldehyde and the preparation of benzoic acid from toluene.

Senderens, like several well-known French scientific workers, was a faithful son of the Church, becoming first an Abbé and later a Canon. Together with Sabatier he was made an honorary fellow of the Chemical Society in March 1920, and he was elected *correspondant* of the Paris Academy of Sciences in 1922.

In Grignard's "Traité de Chimie Organique" (Vol. 3, 941; 1936) there is written: "La catalyse n'a pris de l'importance en chimie organique que per les travaux de Sabatier et Senderens" (1897–1905), a statement which cannot fail to find universal acceptance.

E. K. RIDEAL.

Dr. R. O. Hall

WE regret to announce the death on November 28. as the result of an accident, of Robert Oswald Hall,

Hall was born on June 24, 1905, and educated at Wakefield Grammar School from 1916 until 1923. In 1924 he entered the University of Leeds, where he took the honours chemistry course, holding the Lord Kitchener National Memorial scholarship from 1925 until 1929. Later, he took part in a general study of the hygienic properties of clothing, and investigated the laws governing the transmission of water vapour through textile fabrics as a function of their structure and the nature of the component fibres. An account of the work is to be found in the thesis on "The Ventilating Properties of Textile Materials and Fabrics", for which he was awarded the degree of Ph.D. of the University of Leeds in 1930. In the same year, he was elected an associate of the Institute of Chemistry, and was appointed an assistant chemist in the Government Laboratory.

In 1931, Hall was appointed research fellow of the Textile Department, Ontario Research Foundation, Toronto, where he remained for three years. There he carried on a series of investigations relating to the quality and specifications of textile materials as used in the motor car industry. This work led him into a number of separate lines of research of a fundamental character. Thus, in regard to the colour of fabrics, he devised an instrument by which it was possible to determine the fugitivity of dyestuffs under controlled conditions of temperature and moisture but under intense illumination, which greatly accelerated the fading. He was appointed to draw up standards of fastness acceptable to the two branches of industry concerned.

Other aspects of Hall's work were concerned with standards of length measurement in relation to the atmospheric humidity and hence the moisture content of textile materials. In addition to such problems as these, which were undertaken on account of their immediate importance to industry, he found time to pursue inquiries of a more academic character, particularly an investigation of the absorptive behaviour of the wool fibre in relation to the degree of swelling.

Early in 1934, Hall accepted an offer of the position of research chemist with Messrs. C. W. Martin and Sons, Ltd., Bermondsey, London, S.E.1, in connexion with their processes in dressing and dyeing fur skins.

During the past three years, Dr. Hall carried out fundamental research on the behaviour, under different conditions, of the individual fibres constituting the fur and pelt of skins. For these investigations he worked out a special technique in microscopy which led to some extremely novel and interesting results. Other problems investigated by him included 'singeing' of hairs, bleaching of ermine, and unhairing of fur seals. His abilities as a physicist proved of great value in work connected with the conditioning and drying of skins.

Hall represented the best type of scientific worker, logical, clear-thinking and of wide experience; by reason of these qualities his views commanded respect and attention. His loss will be felt not only by scientific workers who had come in touch with him but also by his colleagues and friends, who were attracted by his cheerful disposition and sound judgment. He leaves a widow and one child.

Prof. J. S. Štěrba-Böhm

BY the death of Prof J. S. Štěrba-Böhm, professor of inorganic and pharmaceutical chemistry in the Charles University of Prague, on January 1 at the age of sixty-three years, Czechoslavakia has lost a distinguished investigator of international reputation. After graduating in pharmacy, Štěrba-Böhm left Prague and travelled through Austria to Serbia, and to Italy, France and Germany. In Paris he was fortunate enough to attract the attention of both Becquerel and Moissan, with whom he carried out some original work.

On returning to Prague, Štěrba-Böhm assisted Brauner in some of his investigations on the rare earths, and this work he continued after the latter's retirement. Meanwhile, an opportunity arose in 1913 and Štěrba-Böhm was appointed assistant professor. After the Great War, in 1919, a chair for pharmaceutical and inorganic chemistry was established for him. He had considerable routine work in connexion with pharmaceutical matters and in 1928–29 was dean of the Faculty of Science, but nevertheless was able to continue his researches and published much original work, mostly in Czech and French journals, on the lesser-known compounds of cerium, scandium and germanium. It was characteristic of him that he took the utmost pains to use the purest materials, a precaution which at first gave his collaborators the impression that progress was unduly slow; but it was one that is most essential in researches on the rare earths. Some years ago he prepared a long list of double oxalates of cerium with meticulous care to ensure the greatest possible purity of the salts obtained. More recently he prepared a number of scandium compounds, in particular the formate and its double compounds. Indeed, he contributed much to the chemistry of this rare metal. With a supply of argyrodite he isolated a whole series of pure germanium salts, bringing up to date the early work of Winkler on this element.

Prof. Štěrba-Böhm was of a retiring disposition but was always willing to put his knowledge at the disposal of his students and colleagues. Like many of his countrymen, he had a command of many languages and was an impressive lecturer. He was honorary foreign member of scientific societies in France, Poland, Jugoslavia and Bulgaria. G. D.

Mr. T. Nelson Dale

T. NELSON DALE, a retired member of the United States Geological Survey, died at his home in Pittsfield, Massachusetts, on November 16, nine days short of his ninety-second year.

Courses in mathematics and mineralogy at the University of Cambridge, petrography under Prof. J. Wolf at Harvard University, field trips under the leadership of Dr. Carl Zittel of the University of Munich to Norway, Sweden, France, Germany and Switzerland, and a stratigraphic and palæontological research problem in the Val de Ledro in the Tyrolese Alps, comprised the systematic part of Mr. Dale's early training. The accuracy of this first geological research, praised by Dr. Zittel and by Dr. A. Bittner of the Austrian Geological Survey, characterized all his later structural and petrographic papers written while he was associated with the United States Geological Survey, from 1880 until 1920. This work was mainly concerned with the Taconic and Green Mountain structural problems, which involved some twelve thousand miles of walking and as much of driving in the most rugged section of western New England. The mapping and the structural sections have been found to be, on the whole, extremely accurate within the area studied. The latter phase of his work with the United States Geological Survey was concerned with the investigation of the granite, marble and slate industries of New England and the United States, the results of which work, published in the Survey bulletins, have long been considered standard references among quarry men as well as in colleges and universities.

WE regret to announce the following deaths:

Major E. E. Austen, formerly keeper of the Department of Entomology in the British Museum (Natural History), on January 16, aged sixty years.

Mr. Wilfred H. Parker, director of the National Institute of Agricultural Botany, Cambridge, on January 11, aged forty-nine years.

Prof. Otto Warburg, formerly professor of botany in the Oriental Seminary, Berlin, lately chief of the Institute of Natural History of Palestine in the Hebrew University, Jerusalem, on January 10, aged seventy-eight years.

WE are glad to state that the announcement, printed in NATURE of January 15 (p. 109), recording the death of Prof. Otto H. Warburg, For.Mem.R.S., is incorrect. Prof. Warburg had been confused in press messages with Prof. Otto Warburg, whose death is announced above.

News and Views

A World Association for Science and Society

AT a time when restrictions are being placed upon freedom of scientific work and speech in some countries, and when the nations look to science for the materials of destruction, the momentous pronouncement of the American Association at Indianapolis is a challenge to science and to society (see p. 169 of this issue). No men of science who, in the words of the corporate resolution passed by the Council of the American Association, "regard the suppression of independent thought and of its free expression as a major crime against civilization itself", can ignore that challenge. Nor is the British Association likely to disregard the invitation to co-operate in forming the nucleus of what will be a World Association for the Advancement of Science and Society—an international 'brains trust'—since it was the success of the Blackpool meeting and its concern for social problems which inspired the recent action in the United States. What the American visitors heard there, in the free and constructive addresses delivered by scientific workers on the effects of science on social problems, convinced them that men of science, with unsealed lips, had a great contribution to make to world order. The symposium on "Science and Society", at their Indianapolis meeting, was their first response. The resolutions of their council, proclaiming a Magna Charta of scientific freedom, reaffirming the democracy of knowledge, and inviting all who could subscribe to the free principles of science to join in world co-operation, carried the lesson of the British Association into world affairs.

THE language of the resolutions is forthright and uncompromising. It will not tolerate intolerance. It demands a free trade in scientific knowledge and the recognition that the object of science is the advancement of the well-being of all mankind. As the *New York Times* said in the leading article endorsing the proposals which Mr. Ritchie Calder made in the *Daily Herald* for a Magna Charta and an Anglo-American nucleus, and which led to the American Association taking it up: "He has not exaggerated. To save science his 'World Association' is needed, an organization which shall indicate how the objective attitude of the laboratory may be applied in governing a people, in breaking down prejudices, in preventing war, in solving problems that mean progress not in one country alone but the world over." It is an ambitious project, but the ideals it propounds are those of science itself. Objectivity in a world of misrepresentation and dangerous prejudices is sorely needed. The social inquiries of the League of Nations' Technical Commission on Nutrition, and its parent body the Mixed Commission of the League, are examples of how the principles of science may be universally applied.

WHILE, however, it is important to provide a platform from which men of science throughout the world can proclaim the truths of science, it is also important that a World Association, to fulfil its objectives, must have the means to initiate inquiries, collect data and be prepared to co-operate with the social forces for peace and progress. In all the vicissitudes of the political history of the League of Nations, the International Labour Office and the Health Organisation have carried on their constructive humanitarian work. A similar organization for science, more effective and far-reaching than the Committee for Intellectual Co-operation, would give substance to the spirit of the American proposals. It would be a World Association, safeguarding the independence of scientific workers and of scientific thought, willing to co-operate with all nations which are prepared to work for the good of mankind, but, as an association, subject to none.

Prohibition of NATURE in Germany

THE declaration of scientific freedom made by the American Association in the resolutions referred to above is a gratifying sign that men of science remain true to the essential condition of scientific progress. That it should be necessary to reassert a principle for which science—as a pursuit for truth—has always stood, is a depressing commentary upon twentieth century events. Until recent years it was believed that the battle for freedom of scientific thought and work had been fought and won, but we are now often painfully reminded of reactionary tendencies. An example of this is afforded by the following translation of an order issued by the German Ministry of Education (Reichserziehungs-Ministerium) a couple of months ago, a copy of which has just reached us: "In the scientific weekly journal NATURE, articles have often been published containing unprecedented and base (*unerhörte und niedrige*) attacks against German science and the Nationalsocialistic State. Therefore this journal must be excluded from general use in scientific libraries. I request that appropriate orders be given to the libraries of the Universities, Colleges, Institutes, and Research Departments. Concerning the secret use and restricted access to the journal I refer to my decrees of the 17th September 1934, 3rd April 1935, and 16th December 1936:—U I 22733, W I e 828, and—W I a 2305."

IT is, of course, altogether untrue to assert that NATURE has ever attacked German contributions to scientific knowledge. Never a week passes without the publication in our columns of appreciative reviews of German scientific works and summaries of papers published in German scientific periodicals, while we are glad also frequently to print original contributions in our correspondence columns. We welcome the opportunity of recording worthy additions to the literature of science or to natural knowledge from any country or any race; but we should be false to the traditions of science if we failed to condemn any influence which would make scientific research subservient to political or theological domination. The misrepresentation of our attitude contained in the announcement of the German Minister of Education is hard to bear, but we regret that the penalty involved in the withdrawal of NATURE from libraries and other institutions will be felt more by some of our readers in Germany than by ourselves.

Science for Peace

A RECEPTION was recently given, jointly by the League of Nations Union and the International Peace Campaign, in honour of the Nobel peace prize award to Lord Cecil. Science was officially represented by Prof. Jean Perrin, who spoke as Under-Secretary of State for Scientific Research to the French Government. A number of well-known British men of science, including Sir William Bragg, were also present. Afterwards Prof. Perrin spoke informally to a small group of scientific workers about the work of the Science Committee of the I.P.C. in France. This Committee, which comprises some seventy men of science, among whom are many of the most eminent in France, has concerned itself with the special relations of science to the problems of peace and war. As Prof. Perrin himself put it, in his Armistice Day address at the Sorbonne: "It must be stressed that we scientists, even more than other men, desire peace, because the very fact of our specialization enables us to realize more vividly what we have to lose from war. Let me make myself clear. Other men defend the happiness of mankind, as they know it; we do so too, and this is certainly enough to justify our effort and our enthusiasm. But apart from this we, who because of our profession can see a little further, are also defending the future of mankind. We are defending the city of the future, that city the form of which is as yet uncertain, where progress will be indefinitely maintained, where justice and fraternity will rule without conscious effort, where illness will have disappeared and death have receded, until it becomes a freely accepted rest, and where each human life will unfold in harmony and beauty. I hope that you will see in this a reason for organizing that peace without which we shall never reach the magnificent realization of that which appears to contemporary man to be the highest ideal."

Indian Science Congress at Calcutta

OUR correspondent, writing from Calcutta on January 9, says: "The Indian Science Congress at Calcutta draws to a triumphant conclusion. The founders of the Congress Association must view with pride the successful outcome of their venture, and the founders of the British Association might well have been proud also, for their work has its continuation not only in the British but also in the Indian and other associations over-seas. The opening of the Congress on January 3 by H.E. the Viceroy was a brilliant occasion. It is understood that membership of the Congress has far exceeded that of any previous meeting, and at the popular lectures given by Prof. H. J. Fleure, Dr. F. W. Aston, Sir James Jeans, Sir Arthur Eddington, and Prof. F. A. E. Crew, the attendances have been enormous: for at least one of them, that by Sir James Jeans, the hall was almost stormed. Very generous hospitality has been afforded by Government authorities, the University and the Corporation of Calcutta, many institutions and private hosts. The time of the delegation has been very fully occupied, not only with the proceedings of the Congress but also in making or remaking those personal contacts for which such an occasion as this offers almost the sole opportunity. A considerable number of the delegates will now proceed from Calcutta to various points in India in pursuance of personal scientific interests and engagements. A party of about fifty, however, are about to leave for six days' travel in the south, during which time they will be formally received by the University of Madras and by the Government of Mysore and the University of Bangalore. They will join the R.M.S. *Strathaird* at Bombay on January 15 for the homeward voyage. The extraordinary good fortune of the delegation in the matter of weather conditions, culminating in the brilliant hours of the visit to Darjeeling, has been recorded in a previous note. At Calcutta these conditions have continued, and it is said that the mean daily temperature has been as much as ten degrees above the normal for this time of year."

Broadcasting and Citizenship

AT the North of England Education Conference on January 6 the Central Council for School Broadcasting and the Central Committee for Group Listening were represented by their secretary, Mr. A. C. Cameron, who discussed the principles on which these two bodies are at present shaping their policies and raised a number of questions as to the moulding and educating influences of broadcasting on the citizen of to-morrow and to-day. As regards school broadcasting, for the reception of which, by the way, in England and Wales some 7,000 schools are equipped, he emphasized its importance as fostering the interest of the child in life outside the school and the interest of the parent in the school. As evidence of the growing interest of parents he mentioned that a school broadcast recently brought him three hundred letters from parents who had listened to it. To promote group listening and discussion seven area councils representative of voluntary bodies, local authorities and the universities have been constituted. Many listening and discussion groups have been formed by such bodies as women's institutes, townswomen's Guilds and public libraries, and many are recognized by local education authorities as eligible for grants for "further education". Another speaker at the Conference, a member of the executive of the National Union of Teachers, argued that wireless receiving sets ought to be regarded as essential pieces of equipment for schools and for bodies such as juvenile organization committees and community centres which undertake to promote group listening as a means of adolescent and adult education. It seems open to question whether grants should be made for encouraging such listening and discussion groups without some sort of guarantee that they are conducted by competent leaders. With proper guidance (for which attendance at university extension tutorial classes would provide an excellent training) such groups could be developed into a powerful agency for education for citizenship.

Psychology of International Relations

IN an address at a public luncheon given by the National Institute of Industrial Psychology on January 13, Dr. William Brown said that the psychology of international relations, otherwise the psychology of peace and war, can be adequately discussed only on the basis of a scientific study of the human mind. Dr. Brown is convinced that the latest war was not the last. He compared it with a manic-depressive patient who, after a state of deep depression, passes into one of exaltation and feels that never again will his old symptoms return. Of a patient of this kind it is known that sooner or later he will have another relapse. Although psychological treatment can benefit such a patient, and in some cases produce recovery, the underlying physical and mental causes of the illness remain obscure. So it is with war and peace. Psychologists cannot yet claim that a solution has been discovered. All they can do is to go on and disentangle the various forces which are at work to produce war. Of these forces, one of the most important is the primitive struggle for existence. It is not possible, however, said Dr. Brown, to deduce the social behaviour of a man from his purely individual behaviour. Man still carries with him tendencies towards more primitive forms of mental reaction such as are appropriate to the early stages of national and social evolution. These primitive forms of reaction are very clearly revealed in criminal behaviour, in panic-stricken flight and in certain mass movements. The possibility of mass mental reactions have an obvious bearing upon the problem of war and peace. For such primitive forces as self-preservation and self-assertion, while valuable in many respects, yet if used in certain ways, are irreconcilable with ultimate peace between individuals or between nations.

Chinese Universities Relief Fund

THE damage inflicted on universities in the course of the Japanese invasion has been enormous, amounting in several instances to complete destruction of all the university buildings and equipment. Concerted action has been taken by students, professors and the Chinese Government to combine the relief of distressed students with the maintenance of some form of training in centres remote from the war theatres, such as Changsha in Hunan Province. Appeals to universities in other lands have been organized by International Student Service for the relief of destitute students and for equipping them in their efforts to carry on their studies. In England there has been a response from every single university and the majority of university colleges, the amount raised in this way up to date being £3,000. The English committee has undertaken, in addition to contributing to the international fund, to assist Chinese students in Great Britain whose funds have been cut off. In a letter to *The Times* of January 7, Sir Walter Moberly, chairman of the International Student Service, appeals for at least another £2,000. Contributions may be sent to Prof. Ernest Barker, the Hon. Treasurer of the Chinese Universities Relief Fund, at 49 Gordon Square, London, W.C.1.

Determination of Molecular and Atomic Weights

A COMMITTEE for the study of the determination of molecular and atomic weights of gases by physico-chemical methods, organized by the International Institute of Intellectual Co-operation assisted by the International Council of Scientific Unions and by the International Unions of Physics and Chemistry, met on December 17 and 18 in Neuchâtel (Switzerland). Two reports formed the basis of the discussion, the first on the method of limiting-pressures, established by Prof. R. W. Whytlaw-Gray and Dr. W. Cawood, the second on the method of limiting-densities, established by Prof. E. Moles. Prof. Jaquerod presided over the assembly, which was attended by Profs. Whytlaw-Gray (Leeds), Moles (Madrid), Lepape (Paris), Klemenc (Vienna), Timmermans (Brussels), Keesom (Leyden) and Dr. Cawood (Leeds). Several suggestions were made concerning the improvement of the methods used, and a discussion took place concerning the interpretation of the results obtained. Among the conclusions, the committee emphasized the international importance of the laboratories at Leeds (Whytlaw-Gray) and at Madrid (Moles), on account of the results they obtain, their equipment and the special qualifications of their staffs. This is to be reported to the International Organisation on Intellectual Co-operation of the League of Nations. The full reports and the minutes of the meeting will be published by the International Institute of Intellectual Co-operation. This meeting was a part of the projected scientific activity of the International Organisation on Intellectual Co-operation. Future assemblies of committees of study will be held this year and the following questions will be discussed: "New Vitamins"; "Nomenclature of Genetics"; "New Theories of Modern Physics"; "Co-ordination of Scientific Terminologies" and "The Electric Double Layer".

Scottish Universities Parliamentary Election

On January 20, a writ was issued for the Scottish Universities by-election, made necessary by the death of Mr. Ramsay MacDonald. A group of strong candidates is in the field: Sir John Anderson, former Governor of Bengal, the nominee of the Unionist Associations of the Universities; Prof. A. Dewar Gibb, regius professor of law in the University of Glasgow, a Scottish Nationalist; Dr. Frances H. Melville, formerly mistress of Queen Margaret College, University of Glasgow, an Independent candidate; and Sir Peter Chalmers Mitchell, biologist and former secretary of the Zoological Society of London, standing as an Independent Progressive. Sir Peter Chalmers Mitchell is a graduate of the University of Aberdeen as well as of the University of Oxford, and he has maintained contact, during a life devoted to biological science and administration, with the arts and with educational developments in Great Britain and abroad. He was secretary of the Zoological Society of London for thirty-two years, and for a long period was leader writer and scientific correspondent of *The Times*. At a meeting of Scottish graduates in London he stated that the principle of university seats in Parliament is most difficult to defend if these are simply to be held by official nominees of the political parties, and that he considers it the duty of university electors to select the candidate with the best qualifications to advocate the services which the arts and sciences can give the nation. Sir Peter is particularly well qualified to present and uphold in the House of Commons the scientific outlook upon modern problems touched by science, and on this account his election to Parliament would be widely welcomed.

Centenary of James Craig Watson

On January 28 the centenary occurs of the birth of the American astronomer James Craig Watson, whose name is recalled by the Watson Medal of the National Academy of Sciences. He was born in Elgin County, Canada, of American parents, and at the age of fifteen years he entered the University of Michigan at Ann Arbor, and there came under the influence of the German astronomer Franz Brünnow (1821–91) who in 1854 had been appointed the first director of the Ann Arbor Observatory. Watson soon became an enthusiastic astronomer and on Brunnow's resignation in 1863 he succeeded him as director of the Observatory and as professor of astronomy. He held these positions until 1879, when he was appointed director of the Washburn Observatory at the University of Wisconsin, Madison, where he died suddenly on November 22, 1880, at the early age of forty-two years. Watson became known by his discovery of the minor planet Eurynome, which he first observed in 1863. Afterwards he discovered twenty-one other similar bodies. In 1867 he published a valuable work on theoretical astronomy which became a standard text-book. He was one of those who journeyed to Sicily to observe the solar eclipse of December 22, 1870, and four years later he visited Peking to observe the transit of Venus, for which event the astronomical world had established some forescore posts of observation at a cost of about a quarter of a million. In 1870, by which year he had discovered seven minor planets, Watson was awarded the Lalande Medal of the Paris Academy of Sciences.

Royal Astronomical Society's Awards

The gold medal of the Royal Astronomical Society has been awarded to Dr. William Hammond Wright, director of the Lick Observatory, Mount Hamilton, California, for his studies of the spectra of gaseous nebulæ and of novæ and for his work on the photography of planets in light of different colours. A bronze ('Jackson-Gwilt') medal and gift have been awarded to Mr. P. M. Ryves for his observations of variable stars and other astronomical work, and also to Mr. F. J. Hargreaves for his contributions to astronomy. The investigations of Dr. W. H. Wright on the spectra of the gaseous nebulæ comprise: (1) measurements of wave-lengths and of intensities of nebular lines; (2) the study of the nebular nuclei; (3) the investigation of the distribution of nebular radiations throughout the nebulæ. Dr. Wright was the first to realize the importance in these observations of accurate guiding, without allowing the object to drift along the slit to lengthen the lines, in order to study the spectra of the nuclei and to derive information with regard to the localization of lines in some of nebulæ. He has recently returned to the study of the spectra of planetary nebulæ in the ultra-violet, taking advantage of the extension to shorter wave-lengths made possible by the coating of the 36-inch mirror of the Crossley reflector with aluminium. Mr. Ryves has for many years been a most assiduous and accurate observer of variable stars, and has communicated fifteen papers on that subject to the Society. Mr. Hargreaves has rendered important services to astronomy by the design of valuable instrumental accessories. He has devised an electric drive for telescopes which has been very successfully applied to the 28-inch equatorial at Greenwich. He also constructed a "comparison image micrometer" with which he made double-star observations with an accuracy which compared very favourably with that of observations made with the filar micrometer. In addition, he has produced mirrors and other work of high excellence. His contributions to astronomical observation have been chiefly in the delineation of planetary detail, but he has given much attention to astronomical photography.

Geological Society of London Awards

THE council of the Geological Society has made the following awards: Wollaston Medal to Prof. Maurice Lugeon, of the University of Lausanne, in recognition of the value of his researches on the mineral structure of the earth, particularly in respect of the geological structure of the Alps and of mountain building; Murchison Medal to Dr. Henry Howe Bemrose, in recognition of his researches upon the igneous rocks of the Lower Carboniferous of Derbyshire, and also upon the Pleistocene fauna of the same area; Lyell Medal to Dr. John Pringle for his services to palæontological science, and particularly in recognition of his work in connexion with the Geological Survey and Museum; Wollaston Fund to Dr. Henry Francis Harwood, of the Imperial College of Science and Technology, in recognition of his research work on the chemistry of minerals and rocks; Murchison Fund to Dr. Frank Coles Phillips, for his contributions to metamorphism and structural petrology; a moiety of the Lyell Fund to Dr. Sydney Ewart Hollingworth, for his work on the Lower Carboniferous rocks, and the structural geology of the Lake District and northern Pennines, and on the Vale of Eden glaciation; another moiety of the Lyell Fund to Dr. Frederick Murray Trotter, for his geological researches, especially on the glacial and post-glacial phenomena of the Eden Valley.

ε Aurigæ—a Super-giant Star

UNTIL the requisite details are available in the *Astrophysical Journal* regarding Dr. O. Struve's discovery of the precise nature of the eclipsing binary system of ε Aurigæ, no useful comments can here be made. It may be inferred, however, from the Press reports that a study by Dr. Struve of the infrared spectrum of the star obtained with sufficiently high dispersion has shown that the chief component of the system is a super-giant star with a radius some 3,000 times that of the sun. The star of largest radius hitherto known is Antares, the radius of which is about 450 times the sun's. ε Aurigæ, the light variation of which is of Algol type but with an exceptionally long period of 27·1 years, has long been the subject of intensive observation, mainly in Germany, in the United States and in Canada. The spectroscopic history of the star up to 1928 is summarized in "Handbuch der Astrophysik", 6, Pt. 2, 466 (1928). Results obtained at the Yerkes Observatory by Frost, Struve and Elvey at the last light minimum in 1928–29 are given in the publications of that observatory in vol. 7, Pt. 2. During the same epoch, Adams and Sanford were able to distinguish clearly on their high-dispersion spectra taken at Mount Wilson a faint component on the redward side of the enhanced lines and those of hydrogen. They pointed out the necessity of obtaining high-dispersion spectrograms of ε Aurigæ at other epochs of the period of light variation in order to trace the origin of the faint spectral component.

Recent Advances in Glass Technology

TWENTY-ONE years ago was a strenuous period for British technologists, and in no field were the problems more urgent than in connexion with the production of glass for laboratory, optical and many other purposes; thus the necessity of team-work brought the Society of Glass Technology into existence, and its coming-of-age has recently been celebrated. A series of lectures on "Glass in Modern Life", arranged by the Society in this connexion, recalled some of the veritable struggles of the period of the Great War, and the more ordered progress of this 'key industry' under the subsequent measure of protection accorded to it. Prof. W. E. S. Turner mentioned that the value of the production of the chemical and scientific glassware industries has risen from £129,000 in 1924 to £250,000 in 1937, and is doubtless even higher today. Undoubtedly, the activities of the Society have contributed in no small degree to the possibility of this expansion, and the same is true of Prof. Turner himself and the Glass Technology Department at the University of Sheffield. The term 'glass' covers a very wide variety of chemical substances; when we find it being employed in these days (*inter alia*) for nuts and bolts, woven fabrics (of course for highly specialized purposes), and bricks for building, we may wonder whether the golden age of glass production is only just beginning. The list of lecturers also included Mr. Raymond McGrath and Mr. Bernard P. Dudding, who dealt with the applications of glass in their special fields of architecture and illuminating engineering respectively; and Dr. W. M. Hampton contributed a lecture on new developments in the field of optical glass. Although the production of optical glass may be a very minor activity from the business point of view, the experience gained in efforts to improve it has been invaluable in its lessons for the larger-scale operations.

Cave Paintings and Military Operations in Spain

WHILE anxiety was felt generally throughout the world as to the fate which was likely to befall the artistic treasures of Spain until reassurance was given by Sir Frederic Kenyon's visit of inspection to the scene of hostilities, archæologists were no less perturbed at the thought of the damage which might be done to the priceless palæolithic paintings of the caves of northern and eastern Spain, both within the zones of operations. In the current number of *L'Anthropologie* (47, 5–6) a note is published from the Abbé Breuil to M. R. Verneau, in which it is stated that Prof. H. Obermaier has been informed by a journalist that the famous cave of Altamira, in the neighbourhood of Santander, the best known and most important of the caves, had suffered no serious injury, although it had given shelter to some hundreds of refugees and the house of the guide had been occupied by an officer of the Red staff. Alcade del Rio also is informed that the same is true of the other caves with paintings of the Cantabrian Pyrenees. On the other hand, M. Verneau is told that the greater part of the archæological collection formed by Sen. Perez de Barradas and housed in the Municipal Museum of Madrid, had been broken up. News of the fate of the important paintings in the province of Teruel in eastern Spain will be awaited with no little anxiety.

Palestine Archæological Museum

THE Palestine Archæological Museum in the newly erected buildings at the north-eastern corner of the city of Jerusalem was opened to the public on January 13, the ceremony, which was to have taken place on January 11 in the presence of the High Commissioner, having been cancelled, owing to the murder of Mr. J. L. Starkey on the previous evening, when on his way to Jerusalem in order to be present. The cost of erecting the buildings has been met in part by a gift of two million dollars to the Government of Palestine by the late Mr. John D. Rockefeller. The site of ten acres, of which the buildings occupy one quarter, was provided by the Government. The architect was Mr. Austen St. B. Harrison. The Museum consists of a central rectangular block, flanked on north and south by buildings around open courts. In addition to the exhibition halls, open to the public, which will house the more striking and important exhibits, galleries are provided for the material which will be accessible to students, while in the basements provision has been made for housing archæological material from excavations and other sources, pending its allocation and distribution. Provision is also made for staff accommodation and library, the latter already consisting of ten thousand volumes, and space being reserved for a further thirty thousand. The Museum will cover the pre-, proto- and historic periods, including the Roman, Byzantine and Arab antiquities of Palestine down to A.D. 1700. Among the antiquities now on view are the Galilee skull, the first Neanderthal skull to be found in Palestine, the remarkable collection of prehistoric pottery dating from the Stone Age to the close of the Canaanitish period, and the ivories from the palace of Ahab in Samaria, discovered in the excavations of 1933–35, which are among the most striking objects of æsthetic interest as yet found in Palestine.

Further Exploration of Tell Duweir, Palestine

APPREHENSION has been felt among archæologists lest the further exploration of Tell Duweir, the Biblical Lachish, should have to be abandoned, owing to the murder of Mr. J. L. Starkey, the director of the Marston-Wellcome Archæological Expedition to the Near East, by whom the mound was being excavated. The death of Mr. Starkey is universally regarded as an irreparable loss to Palestinian studies; but the blow would have been even heavier had it not been possible to continue work on this important site, which has already provided so much valuable material bearing on the interpretation of more than one crucial period in the history of the country and its cultural development. This fear has now been allayed by the announcement that the excavation will continue, at any rate for the present. Arrangements have been made by the High Commissioner for it to be carried on under the supervision of Mr. Lankester Harding, who was recently appointed director of antiquities in Transjordania. Mr. Harding was Mr. Starkey's principal assistant in 1932–36. He is, therefore, not only well acquainted with the character of the site and the lie of its stratification, but also—and this is of no little importance—he is thoroughly familiar with the scheme of operations, which Mr. Starkey had plotted out in relation to the importance of the areas to be excavated, so far as this could be gauged in advance.

Indian Universities and Nationalism

THE annual Patna convocation lecture was delivered on November 27 by the vice-chancellor of the parent university of Calcutta, Mr. S. P. Mukherjee. The lecturer, although disclaiming for himself the qualifications of a historian, declared that Indian universities should saturate their alumni with the lessons of Indian history and civilization, and took as his principal theme an interpretation of Indian history coloured to stimulate the "ever-increasing vitality of Indian nationalism" with somewhat bitter references to present "bondage" and "a subject race and the power that wants to hold it in its leading strings". It seems regrettable, though not surprising, that the Indian universities should under the new constitution allow themselves to be used for the purposes of political propaganda. Lord Willingdon recently remarked that Indian politicians used to believe we were not sincere in wanting to help them in their advance towards responsible government but that they trust us now. No such change of heart seems to have been experienced by Mr. Mukherjee.

Earthquake Records at De Bilt

DR. E. VAN EVERDINGEN'S twenty-second report on the work of the seismological station at De Bilt continues, for the year 1934, the useful lists in its predecessors (*K. Nederl. Meteor. Inst.*, No. 108; 1936). The station lies about five miles north-east of Utrecht and is provided with horizontal and vertical Galitzin seismographs in addition to Wiechert and Bosch seismographs. The report contains the times as recorded at De Bilt of the different phases of 487 earthquakes, and in most cases gives also useful details on the position of the epicentre, as determined by the records at different observatories, the places at which the earthquake was felt and the intensity at them when known.

King George VI Sound

ONE of the most important discoveries of Mr. J. Rymill's recent British Graham Land Expedition was the discovery of the remarkable narrow sound which appears to separate Alexander Island from the main Antarctic continent and to extend for some two hundred and fifty miles in a north and south direction. *The Times* announces that this feature, by permission of the King, has been named King George VI Sound. It would appear to make not only a physiographical but also a structural division, since the rocks to the east are volcanic while those to the west, in Alexander Island, are fossiliferous sedimentaries which are probably related to the rocks of the Andean folds of Graham Land in general.

A Large Sunspot

A BRIEF scrutiny of the sun's disk on January 15, made possible at Greenwich in a break of persistent cloud, showed that a big sunspot had appeared. The approximate time of the central meridian passage was January 18·4, the latitude of the spot being 19° N.; its area was estimated to be about 2,500 millionths of the sun's hemisphere. The spot, which resembles the giant spot of last October, will reach the sun's western limb on January 24. A magnetic storm was recorded at Abinger commencing on January 16 at $22{\cdot}6^{h}$.

Dr. H. L. A. Tarr

DR. H. L. A. TARR, of the Rothamsted Experimental Station, has been appointed to the Sir William Dunn Institute of Pathology, University of Oxford, where he will carry out research on the chemistry of the bacteria responsible for certain human diseases. During the past four years he has been in charge of the investigations on the brood diseases of bees at Rothamsted and accounts of his work have appeared regularly in the various English bee journals and in scientific periodicals. Dr. Tarr went to Rothamsted early in 1934 with a considerable and varied previous experience in bacteriological work. He had been connected with the Department of Dairy Bacteriology at the University of British Columbia and the Departments of Pathology and Industrial and Cellulose Chemistry of McGill University in Canada, and, immediately before taking up his position at Rothamsted, worked for three years under Sir Gowland Hopkins in the Sir William Dunn Institute of Biochemistry, Cambridge.

New Sundials at the Science Museum

Two portable sundials of considerable interest have recently been acquired and placed on exhibition in the Time Measurement Section of the Science Museum. The first is an ivory column or 'pillar' dial dated 1587, designed for use in a latitude of 44° and indicating hours on the old Italian system in which the day-and-night period was divided into 24 equal parts, starting from sunset. The second dial is a 'universal' one, adjustable for use over a wide range of latitudes; it is by Dollond, the well-known eighteenth century London maker, and has been presented to the Museum by Mr. J. Bentley Bennett.

Announcements

THE Right Hon. Neville Chamberlain, M.P., Prime Minister; the Rev. M. E. Aubrey, general secretary of the Baptist Union; and Viscount Nuffield, chairman of Morris Motors, Ltd., have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for their public services.

DR. P. LEWIS-DALE, chief chemist of the L.M.S. Railway, has retired; he is succeeded by Mr. W. P. Henderson, assistant chief chemist (Horwich). Mr. H. Hayhurst succeeds Mr. Henderson as chief chemist of the research department at Horwich.

DR. C. G. SELIGMAN, emeritus professor of ethnology in the University of London, is leaving in a few days for Yale University, where he will occupy the post of Bishop Museum visiting professor for the second semester of the present academic year. He will lecture on New Guinea, particularly that part (now called Papua) which used to be known as British New Guinea. Dr. Seligman will be at Yale until early in June, and his address will be: Hall of Graduate Studies, Yale University, Newhaven, Conn., U.S.A.

DR. F. M. R. WALSHE has succeeded Dr. Gordon Holmes as editor of *Brain*.

A SHORT course on industrial physiology and medical industrial psychology will be held at the London School of Hygiene, Keppel Street, W.C.1, on February 7–18. It is designed for members of the supervisory staff in industry, but may also be of interest to industrial medical officers. Further information can be obtained from the Secretary of the School.

THE seventh International Congress of Genetics will be held in Edinburgh in 1939, probably on August 23–30. Prof. F. A. E. Crew, Institute of Animal Genetics, University of Edinburgh, Edinburgh, 9, has been appointed general secretary to the Congress and to him all correspondence concerning it should be addressed.

THE Ducheune de Boulogne Academy, which aims at rewarding independent workers in honour of the memory of the celebrated neurologist, has recently awarded its annual prize of 10,000 francs to Dr. Louis Bory for his work on general, experimental and comparative pathology, the chemotherapy of sulphur, and dermato-syphiligraphy. Further information about the prize can be obtained from the Secretary of the Academy, 28 bis rue Saint-Dominique, Centre Marcellin-Berthelot, Paris.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 165.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

A New Monochromator

IT is well known that chromatic polarization can be used for the purpose of obtaining colour-filters. In general, such a filter can be used only for selecting a very broad region of the spectrum.

R. W. Wood[1] showed in 1914 that a thick quartz plate between two polarizing prisms is a suitable means of selecting one of the D-lines in the spectrum of sodium. A bright interference band was placed on one of the components and a dark band on the other component. This arrangement proved very useful in the study of resonance radiation.

In connexion with work of this kind, the new 'Polaroid' film invented by E. H. Land offers interesting possibilities. I have constructed a new type of monochromator which is built up of a number of 'Polaroid' films with intermediate quartz plates. In this way a small spectral region can be isolated in a continuous spectrum.

Suppose, for example, that we want monochromatic light of the wave-length λ_0. We then take a number of quartz plates all giving a bright band at λ_0. If the thickness varies from plate to plate as 1 : 2 : 4 : 8, etc., and if the quartz plates are placed with their principal directions making an angle of 45° with the vibration axes of the parallel 'Polaroid' films, the whole spectrum will almost disappear except for some widely separated narrow bright bands. It is not difficult to find an ordinary colour filter which absorbs all these bands except the one at λ_0.

It is easy to calculate the intensity distribution in a spectrum transmitted by such a filter. If the polarization is complete, the intensity $I(\lambda)$ at the wave-length λ is given by :

$$I(\lambda) = \cos^2\frac{\varphi_1}{2}\cos^2\frac{\varphi_2}{2}\cos^2\frac{\varphi_3}{2}\;\ldots\;\cos^2\frac{\varphi_m}{2},$$

where

$$\varphi_m = \frac{2\pi d_m}{\lambda}\,\Delta n\,;\ \text{etc.}$$

Here d_m is the thickness of the plate m and Δn the difference in refractive index for the extraordinary and ordinary rays.

Fig. 1 shows the effect produced by four quartz plates. The calculation has here been made for crossed 'Polaroid' films ($\sin^2\frac{\varphi}{2}$ instead of $\cos^2\frac{\varphi}{2}$). In this case there is a small displacement between the maxima produced by the different plates which does not appear for parallel Polaroid films. The parallel films are therefore to be preferred.

I ordered an instrument of this kind from Steeg and Reuter in Bad Homburg in the beginning of May this year. The instrument was delivered only the other day and has now been tested in the laboratory. The instrument consists of five Polaroid films (delivered by Polaroid Products, Ltd., London) and four quartz plates of the following thicknesses : 5·1808 mm., 2·5904 mm., 1·2952 mm. and 0·6476 mm. On each side is an ordinary colour filter (Jena $R.G.$ 2). The filter was intended to give the wave-length of $H\alpha$ (λ 6563).

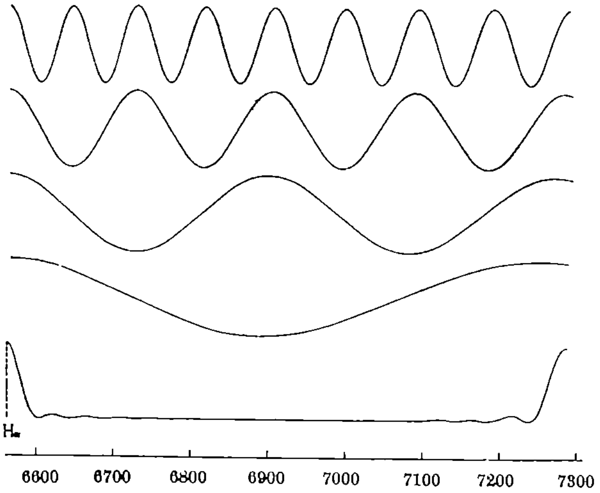

Fig. 1.

The filter has proved to be very good indeed. In Fig. 2 is the spectrum of an ordinary electric lamp and that of neon as comparison, obtained with a one-prism spectrograph. The dispersion around $H\alpha$ is only about 300 A./mm. The left image is a long exposure showing a broad line and one 'satellite' at the side. The right image shows only the central line.

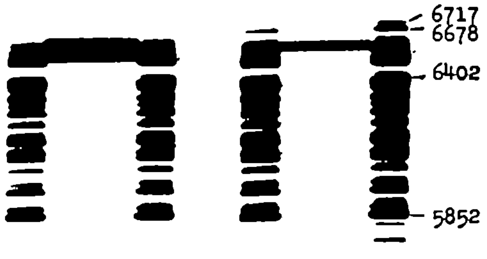

Fig. 2.

Fig. 3 was obtained with a grating spectrograph at the Physical Institute of the University of Stockholm. (I am indebted to Dr. Grundstrom for valuable help with the exposures.) The dispersion is here 5 A./mm. The central image was obtained by photographing a continuous spectrum with the filter at normal incidence. It shows the intensity maximum at about λ 6580. In the upper image the filter has been tilted 19°. This image shows stronger 'satellites' and the maximum has been shifted about 100 A. towards the violet.

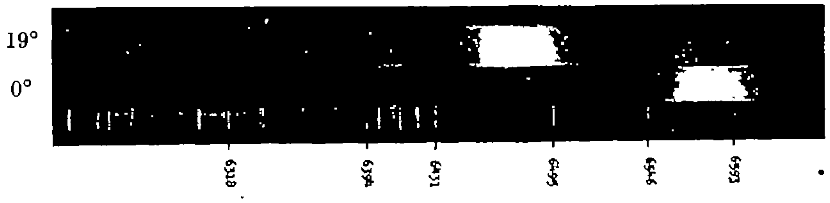

Fig. 3.

Fig. 4 shows the spectrum obtained when the filter is inclined about 9°. Now the maximum coincides with $H\alpha$, photographed above. But the monochromator has not been tilted in the most favourable way, which is around one of the principal directions of the quartz plates.

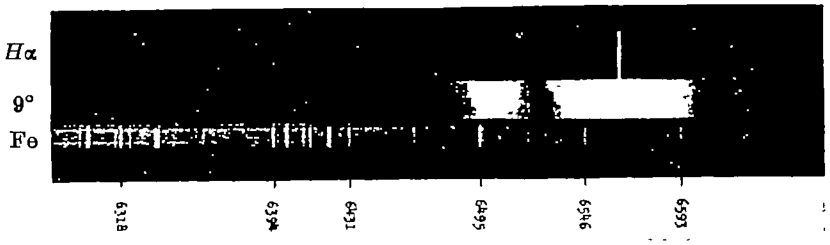

Fig. 4.

The new filter may be used for different purposes. It transmits almost only one single band in the spectrum, of a width of about 50 A. The loss of light is moderate and the definition of the images viewed by it is astonishingly good considering the many layers through which the light has to pass. For many purposes it is an advantage that the transmitted light is polarized. It is an advantage, too, that the wave-length can be adjusted by tilting the filter.

I intended to use this instrument for observing solar prominences. *Observations made to-day have shown prominences without difficulty although the altitude of the sun was only* 10°. The instrument was put after the eyepiece of a 20 cm. refractor and the sun itself was screened by means of thin sheet-metal in the focal plane of the 20 cm. lens. The instrument looks very promising for this purpose. The advantage is that the field of view is not limited by a slit as in ordinary spectroscopes.

YNGVE ÖHMAN.

Stockholm Observatory.

Evidence of Abnormal Behaviour of NO_3 in the Cubic Crystal, $Ni(NO_3)_2 \cdot 6NH_3$.

WHEN an excess of concentrated ammonia is gently added to a concentrated solution of nickel nitrate in water, crystals of blue (somewhat violet) octahedra are obtained, the correct composition of which was first determined by Wyckoff[1]. The crystal is cubic; the size of its unit cell and the number of molecules contained in the cell were established by Wyckoff by the Laue method of X-ray analysis. But his proposed structure does not appear to be satisfactory, according to Kracek and his co-workers[2], who concluded that the nitrate group NO_3 might be rotating in the crystal and possess spherical symmetry.

I have taken some powder photographs and a series of oscillation photographs of the crystal, all of which show the crystal to have a face-centred lattice in agreement with Wyckoff's observation. But the oscillation photographs further show that reflections *hkl*, *hlk*, etc. have identical intensities, which implies that the crystal has holohedral Laue symmetry $m3m$ and not paramorphic hemihedry $m3$. The correctness of this observation can scarcely be doubted because two other modifications of the crystal at low temperatures, one at about −100° C. and the other at liquid air boiling point, were also found to have the same Laue symmetry, though their structures are quite different as revealed by the spectra on oscillation photographs of these modifications taken by a low-temperature oscillation camera constructed by me. Consequently the crystal at room temperature must have space group $F\bar{4}3m$, $F43$, or $Fm3m$. But none of the three has a symmetry consistent with that of the nitrate group in the cell if each NO_3 group is assumed to be an entity. Since chemical evidence demands independent NO_3 groups, we are forced to conclude that the behaviour of NO_3 in this crystal must be abnormal.

Different abnormal models were then tested by comparing the calculated intensities of reflections with the observed ones recorded on powder photographs of copper $K\alpha$ radiation, taken by a precision Debye-Sherrer camera of large diameter and measured by a precision micro-photometer. The following structure is found to be most reasonable and able to explain the observed intensities most satisfactorily. The structure is based on space group $F\bar{4}3m$ and has, roughly speaking, the CaF_2 grouping with Ca atoms replaced by $Ni(NH_3)_6$ groups and F atoms by NO_3 groups. Fig. 1 is a diagrammatic representation of one octant of an individual cell of such a structure. The plane triangular NO_3 group is oscillating about a line passing through the average positions of the centres of the two oxygen atoms indicated in the diagram by O_1, with the third oxygen atom O_2 alternating between two extremities which belong to the same equivalent group of the space group as the positions occupied by the two O_1's. The configuration of equivalent NO_3 groups in different unit cells is supposed to be not always the same; its two O_1's may occupy any two of the four equivalent points in the octant, that is, the two points occupied by O_1's and the two ends of the arc described by O_2 in Fig. 1.

As all the possible configurations are equally probable, random distribution of NO_3 among them gives the loci of the centres of its oxygen atoms a macroscopic average appearance like that shown in Fig. 2. The locus of the N centre appears as if the atom has a big heat motion. It is interesting to note that the theory of space groups and the definition of the unit cell do not strictly apply to this structure.

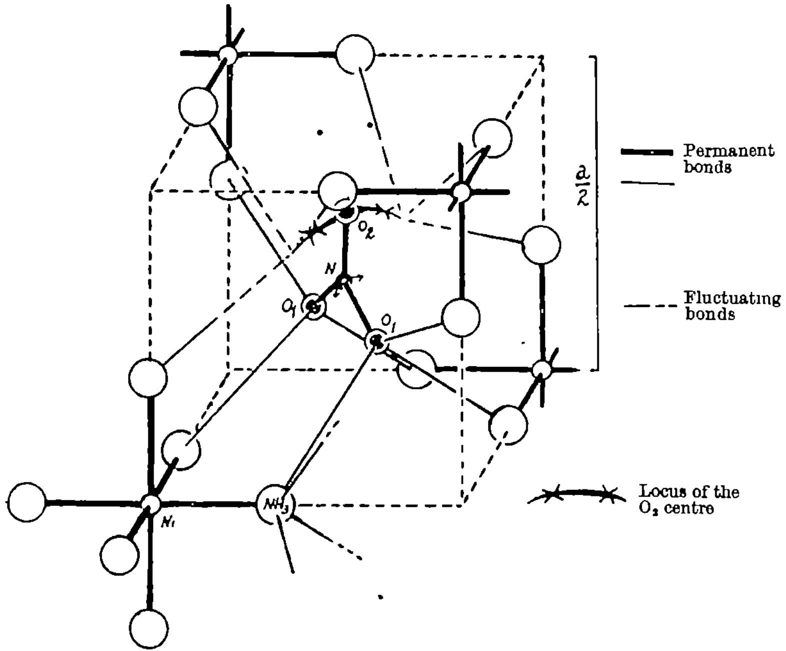

Fig. 1.

To give further evidence of the proposed structure, the signs of the structure amplitudes of the reflections, $F(hkl)$, have been determined in the following way. According to Bradley and Rodgers[3], f-values of the Ni atom for cobalt $K\alpha$ radiation are almost normal, while those for copper $K\alpha$ radiation should be depressed by 3 units. In this crystal proper choice of the origin of reference will make contributions of Ni atoms to all reflections positive. If $F(hkl)$ is positive, it should be bigger for cobalt $K\alpha$ than that for copper $K\alpha$ radiation. If $F(hkl)$ is negative, the result should be the reverse. Hence a comparison of the observed intensities of reflections for the two radiations enables us to fix the signs of the $F(hkl)$'s. The result obtained in this way is in complete agreement with the result calculated on the proposed structure.

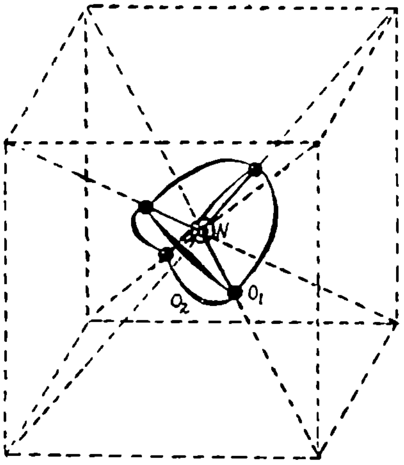

Fig. 2.

Another striking feature of this crystal is that the atoms in it have heat agitation of extraordinary magnitude. The rapid decrease of intensities of reflections with the increase of their glancing angles must be due to enormous heat motion of the atoms in the crystal. This is supported by the increase of intensities of reflections of large angle in the low-temperature oscillation photographs. This enormous heat motion of the atoms in the crystal may be correlated with the abnormal oscillation of the nitrate groups mentioned above.

Two other observations may be worth mentioning. When the crystal is cooled down to liquid air temperature, it is found from the oscillation photographs that it contracts into the −100° C. modification, and then expands into the liquid air temperature modification, of which the density is even smaller than that of the room temperature modification. The colour of the crystal exhibits a marked change from blue (somewhat violet) to dark purple and then to brilliant pink during the cooling. Owing to the preceding abnormalities of the crystal, it might be interesting to study its absorption spectra, as well as its heat capacity at different low temperatures.

Details of the work will appear elsewhere.

I wish to express my sincere thanks to Prof. W. L. Bragg for his interest and valuable advice in this work.

The Lorentz Polarization Term and the Earth's Magnetic Field in the Ionosphere

FOR some years, there has been doubt concerning the value of the accelerating force acting on an electron in the ionosphere under the influence of an electric wave. In 1929, Hartree[1] gave reasons for believing that to the field of the wave must be added a resultant field due to the other electrons present, and showed that this could be accounted for by including a term l of value 1/3 in the derivation of the dispersion equations. The equations then became closely analogous to those first deduced by Lorentz for the propagation of light in a body composed of molecules. The term was afterwards included in a great number of published works on wave propagation in the ionosphere.

In 1934, Darwin[2] gave strong theoretical reasons for believing that the value of l in the ionosphere was zero. The settlement of the point is of considerable practical importance, since measured values of electron density in the ionosphere may be in error by 50 per cent if the wrong value of l has been used. Several unsuccessful attempts to find a crucial experimental test[3] have already been made. We have recently obtained what we believe is decisive experimental evidence in favour of the view that l is zero in the F region of the ionosphere. This conclusion has been reached from the study of a number of records similar to those reproduced herewith, which show the radio echoes obtained from the ionosphere at 0045 hours E.A.S.T., on August 28, 1937, over a frequency range of 0·9–1·30 mc./s. In the figure the lowest uniform trace is made by the ground pulse and so indicates ground-level. At the lower frequencies two upper traces are visible, both representing echoes coming from approximately the height at which the F region is normally found. As the frequency is increased, the lower of these traces rises very gradually, and in fact it is found (though this is not shown in the illustration for reasons of space) that it rises steeply only when the penetration frequency of 6·0 mc./s. is approached. On the other hand, the upper trace is seen in the figure to rise rapidly and is no longer recorded at frequencies greater than 1·27 mc./s. This upper trace exhibits a similar behaviour on all nights when it is observed, invariably disappearing suddenly at frequencies just below 1·30 mc./s. We have arranged for the emitting and receiving systems to have their maximum sensitivities at frequencies just above 1·22 mc./s., but while this has resulted in the recording of a weak echo from the E region at 130 km., and of numerous multiple echoes corresponding to the lower F trace, the 12th of which is seen just below the ground trace after being retarded right round the semi-elliptical time scale, yet we have not been able to record further evidence of the upper echo at frequencies above 1·27 mc./s.

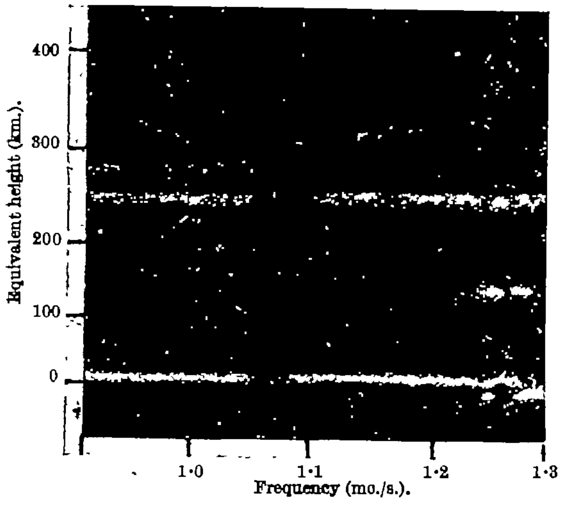

Fig. 1.

Equivalent height - frequency curves obtained by means of radio echoes from the ionosphere over a range of frequencies below the Larmor gyro-frequency. The obliteration of the record at 1·07 mc./s. is caused by interference from a broadcasting station.

The regular nightly disappearance of this echo just below 1·30 mc./s., although the critical penetration frequency of the F region is much higher and variable, leads us to believe that we are here faced with a phenomenon distinct from that normally associated with the penetration of a region of maximum ionization. We have found an interpretation of the existence and abnormal behaviour of this upper echo from consideration of the dispersion curves of an electron medium in a magnetic field H at frequencies slightly below the Larmor gyro-frequency He/m. Ratcliffe[4] has shown that at such frequencies, for $l = 0$, an infinity in μ occurs in the dispersion curve of the ordinary wave, for values of electron density N_2 greater than those (N_1) which give the first reflection point ($\mu = 0$) of the wave. We find that when an appreciable amount of energy of the ordinary wave gets past this first reflection point, it will be largely reflected deeper in the ionized region at the level where the electron density is N_2. A similar conclusion has also recently been reached by a group of workers at Allahabad[5], who show theoretically that the group velocity of a vertically incident ray becomes zero at densities equal to N_2.

From Ratcliffe's work it may easily be deduced that

$$N_2 = m\,(f_1^2 - f^2)/4\,\pi\,e^2\,(f_1^2 \cos\theta - f^2)$$

where $f_1 = H\ e/m$, f is the frequency of the wave, and θ is the complement of the inclination of the earth's magnetic field H. It follows that as f approaches the value $f_1 \cos\theta$, an increasing amount of ionization is required to produce the second echo. When $f = f_1 \cos\theta$, the necessary ionization is infinite. At Sydney the value of f_1 is 1·63 mc./s. at ground-level, and $\cos\theta$, which is independent of level, has the value 0·895. If we suppose that the magnetic field varies inversely as the cube of the distance from the earth's centre, then at a height of 230 km., $f_1 \cos\theta$ is 1·30 mc./s., which is the frequency just below which the upper echo invariably disappears.

It seems clear, therefore, that the upper trace in the accompanying illustration is to be identified as due to this second component of the ordinary wave.

Now, if l be given the value 1/3 in the dispersion equations, no second reflection point of this type is found to occur. The experimental discovery and the identification of the second ordinary echo seems, therefore, definite proof that the Lorentz polarization term l is zero in the F region of the ionosphere.

Theoretical investigation shows that the trace of the second echo should tend asymptotically to infinity on the height scale extremely rapidly, at a frequency f' slightly below $f_1 \cos\theta$. This suggests that if f' can be measured accurately, then a powerful means of measuring the earth's magnetic field in the ionosphere would become available. The small correction $f_1 \cos\theta - f'$ is accurately known in terms of the penetration frequency of the region. The only available method[6] of measuring H in these regions at present is inherently incapable of much accuracy, since it depends on the measurement of a small difference between two large numbers, expressing the penetration frequencies of the ordinary and extraordinary waves respectively.

With the object of making such measurements accurately, we are at present constructing improved equipment in the hope of recording the asymptotic upward trend of the second echo. This work, which will be more fully described elsewhere, is published by permission of the Radio Research Board of the Commonwealth Council for Scientific and Industrial Research.

New Pallial Sense Organs in Early Fixed Stages of *Ostrea edulis*

A careful study of sections of newly attached spat of *Ostrea edulis* has revealed the existence of a pair of organs, apparently of a sensory nature, one in each mantle, of a type hitherto undescribed so far as I am aware. These sense organs are not present in the free-swimming larva before attachment, but begin to develop immediately after fixation and are apparently fully developed in the spat three or four days after attachment.

The sense organs are situated on the inside border of the thickened free edge of the mantle, about one third of the length of the free edge from the mouth. In section, each sense organ appears as a thin-walled spherical pigmented sac of epithelium projecting from the inside mantle surface and containing in the cavity a comparatively large concretion which stains vividly with eosin (Fig. 1, *b*). The concretion is not calcareous as it is unaffected by decalcification. Nor does it appear to be siliceous. Each concretion is made up of a large number of small granules, loosely aggregated in the early stages of development, but in older spat closely compacted to form a roughly spherical mass. No cilia can be detected on the inside of the epithelial sac.

The development of these sense organs may be easily followed in sections of recently attached spat. In spat which have been attached for less than 24 hours, a flask-shaped mass of eosinophilous granules may be seen in the epithelium of the outer surface of the mantle, underlying the shell and apparently opening to the exterior. This situation suggests their derivation from one of the unicellular glands which secrete the shell. This view is strengthened by the occurrence of an epithelial nucleus among the granules of secretion. In slightly older spat, up to 48 hours after attachment, this mass of secretion occupies a position between the inner and outer epithelia of the mantle (Fig. 1, *a*). At the same time the inner mantle epithelium becomes raised up into a dome-shaped protuberance and a split appears in the tissues underlying it. The epithelium covering the cavity becomes charged with black pigment granules. The split later enlarges and becomes the cavity of the sense organ. The mass of secretion becomes rounded off, leaving behind a few granules, and sinks into the cavity underlying the dome of epithelium. In later spat the cavity is enlarged and the epithelium covering it is extremely attenuated and densely pigmented. In the cavity there may frequently be seen one or two nuclei which have become isolated during the formation of the sac. In spat which have been attached four to five days, the most advanced among the material available, these nuclei have disappeared and the cavity is occupied only by the rounded mass of secretion. This would appear to be the fully developed condition of these organs. Exceptionally, two masses of concretion have been observed in a single sac.

In endeavouring to assign a function to these organs, it has to be remembered that the larval statocysts persist in the spat of *Ostrea edulis*, an observation first made by Carazzi[1], and now confirmed by me. These statocysts are, however, comparatively deeply seated within the body of the spat oyster and do not appear to be in a position to appreciate small disturbances in the surrounding medium. On the other hand, the pallial sense organs here described, situated as they are on the border of the mantle, and separated from the external medium by an attenuated epithelium only, would appear to be suitably constructed and in a favourable position for receiving and reacting to vibrations caused by disturbances in the surrounding water. The value of such organs to a fixed form like the adult oyster is obvious. It would be interesting to know whether such organs exist in other lamellibranchs in which the adult stage is fixed.

Selective Thallium Moult in Sheep

It is known that sheep may be divided into two large groups according to the structure of their wool. The first group includes cultural races of sheep, the wool of which is homogeneous on the greater part of the body, that is, consists of identical fine curling wool fibres (merino and others). The second group includes a number of country unimproved races of sheep with coarse wool, which consists of fibres of different types, kemp and intermediary (mixed-woolled sheep).

I have already shown the possibility of stimulating in sheep a synchronous shedding of wool by treatment with a single dose of thallium compounds. This phenomenon was given the name of 'experimental thallium moult'[1]. In fine-woolled sheep this phenomenon has already been described[2]. I am now able to report the possibility of obtaining an analogous experimental thallium moult in mixed-woolled sheep.

Since mixed-woolled sheep are characterized by the heterogeneity of their fleece, their experimental moulting may *a priori* be thought of in at least two forms: (*a*) first case—a general shedding of the fleece ('general moult'); (*b*) the shedding of certain types only of wool fibres. We have obtained both these possible forms of experimental moulting in mixed-woolled sheep.

The experimental sheep belonged to the following races of mixed-wool sheep bred in the U.S.S.R.: the fat-rumped sheep of Casakhstan, the Russian-Wallach sheep of the North Caucasus, the chushka-Karakul of the Ukraine, the northern small-tailed sheep of the middle Russia, the fur Romanov sheep (Moscow region), the Armenian sheep, Balbas and Masekh. The experiments were carried out both at the Laboratory in Moscow and under farm conditions (Sovkhozes). The total number of mix-woolled sheep treated with different thallium compounds was 839 and that of untreated control ones 869.

The shedding of certain types of wool fibres while other types of wool fibres remained unchanged was called 'selective or differential experimental moult'.

The course of the general experimental moult in mix-woolled sheep is identical with that in fine-woolled sheep described elsewhere.

The selective experimental moult is a peculiar reaction of the fleece that may be considered morphogenetic. Since fine wool and kemp differ in their structure, they may be expected to differ in their physiological properties as well. We supposed that the differences in the form and the structure of the various types of fibres should be accompanied by functional differences.

Engels'[3] and Spencer's[4] work on the connexion between form and function was the basic hypothesis for our study. These *a priori* theses of dialectical logic led us to study the influence of different doses of thallium acetate upon the heterogeneous fleece.

A number of experiments showed the different heights of the thallium threshold of the fine wool and the kemp fibres. With doses exceeding 12–13 mgm. the fat-rumped mix-woolled sheep shed both their kemp and their fine wool. With doses of 8·5–9·5 mgm. the root strength of kemp remains unchanged, while the fine fibres undergo a diminution of their root strength and consequently fall out. Hence the thallium threshold is approximately 11·5 mgm. for the kemp and about 9·0 mgm. for the fine fibres (stall keeping). This difference in the height of the thresholds for the kemp and the fine wool shedding is the theoretical basis for the realization of the selective moult of fine wool alone.

In a selective moult, the fine wool is always more or less mixed with a certain quantity of intermediate fibres or even of single broken kemp fibres. In the same way the kemp fibres which remain upon the body of the animal contain a certain admixture of fine wool fibres. The wool taken off as a result of a selective moult and containing chiefly fine wool fibres was given the name of 'fine fraction'. The wool which remains on the body of the animal was named 'coarse fraction'.

The effect of the selective moult in fat-rumped mixed-woolled sheep of Casakhstan is as follows: A normal 'original' wool cover proper to this race contains on an average 52·05 per cent of coarse and 47·95 per cent or even 31 per cent of fine wool fibres. The fine fraction contains 12·6–14·9 per cent of coarse and 85·1–87·4 per cent, in some cases 92–95·8 per cent, of fine fibres. The coarse fraction contains 80–93·1 per cent of kemp and 6·9–19·8 per cent of fine fibres.

Similar results are obtained with other races of sheep.

The experiments on selective moulting in sheep which we have carried out may be considered from both the theoretical and the practical points of view.

Selective moulting, as a peculiar morphogenetic reaction, is a proof of the possibility of a *physiological distinction between morphologically different structures* ("Morphologische und physiologische Erscheinungen, Form und Funktion bedingen einander wechselseitig" (Engels[3])).

Hence selective moulting is an excellent subject for the study of the part played by chemical agents in morphogenesis. It may, moreover, be considered as a *method of analysis of living matter* by means of the action of chemicals and pharmacons. These two methods demonstrate the theoretical importance of selective moulting in biology.

Selective moulting has obvious prospects of economically important industrial applications. The country mixed-woolled races are often very valuable because adapted to the climatic conditions and are utilized in many ways (for milk, flesh, fat, etc.). Their wool is of but small value because of its coarseness and heterogeneity. Nevertheless, the fine wool fibres contained in the fleece of sheep with heterogeneous wool does not greatly differ from the wool of fine-woolled sheep. Selective moulting makes it possible to obtain from coarse-woolled sheep with mixed wool, a fine wool approaching or even equalling merino as to wool quality. The only obstacle to a wide application of this method is the presence of certain harmful by-effects, which we shall describe elsewhere.

Functions of the Tube in Sabellid Worms

Spirographis spallanzanii Viviani and *Sabella pavonina* Savigny live in tubes made of a mucoid secretion mixed with mud. The animals are negatively thigmotropic, negatively geotropic and positively phototropic. The tubes, after the animals have been removed from them, cannot be stretched, but they can easily be bent. The tubes, however, are completely elastic in that they return at once to their initial shape after bending. In spite of this, the animals can bend their tubes permanently into new curves in the course of their various tropisms. To bend such a tube permanently it would be necessary to soften it; this is probably the function of the external digestion of the tube which I previously described[1]. The innermost lining of the tube is more elastic than the rest, and the new curvatures would be produced by a combination of softening with the deposition of new elastic tube substance within the concave side of the bend.

Removed from their tubes, *Spirographis* and *Sabella* are incapable of making new ones. Tubeless worms can be kept alive indefinitely in aerated sea-water, but in water deficient in oxygen they die, whereas worms with their tubes live in this water. We thus have the apparent paradox that a worm exposed on all sides to the water dies of asphyxia, while a worm whose body is enclosed in a tube can breathe and live.

Sabella and *Spirographis* can be removed from their own tubes and put into glass tubes. They line the glass tube with a secretion, and lengthen it with normal tube material. Such worms in glass tubes will live in conditions of oxygen deficit which kill naked worms. Observation of *Spirographis* in glass tubes has given a probable reason why naked worms are less viable than those in tubes. Inside its tube the worm executes rhythmic movements, which must continually renew the water in contact with the body. At regular intervals a swelling of the body wall, completely filling the tube, forms at the hind end of the worm; this swelling moves forwards. In the case of tubeless worms there are scarcely any such movements, and the animals are probably asphyxiated because of a stagnant layer of water in immediate contact with the body.

Tubeless worms can live in aerated water; presumably they are able to do so in spite of the absence of vigorous body movements because there is more than enough oxygen for them in the water. Worms in their tubes execute the rhythmic movements even in fully aerated water; the result of this must be that the small amount of water in the tube is continually renewed, and presumably it is necessary for the worm to renew this water even when the surrounding sea-water is fully aerated. These observations show that the tube has a second function besides that of protection: it provides the mechanical stimulus for the reflex body movements necessary for respiration.

The metabolism of *Spirographis* removed from its tube falls very considerably. On the same day that worms are taken out of their tubes their oxygen consumption decreases to three quarters, and on the following day to one half, of its previous value, while the ammonia excretion falls on the day of removal from the tube to four fifths of its previous value. This fall in metabolism is probably due in large part to the absence of vigorous rhythmic body movements.

A Curious Case of Supposed Silicon Poisoning in the Swan

DURING March 1936, a swan was received from the Belle Vue Gardens, Manchester, at the Harper Adams Agricultural College, where I was working, with a note that it was one of two or three waterfowl which had all died recently on a particular pond. Post-mortem examination revealed nothing abnormal except an acute enteritis most marked in the duodenum but spreading into the middle third of the intestine. All the other organs were healthy and a bacteriological examination proved negative.

Examination of the bowel contents showed no parasites, protozoan or otherwise, to be present, but large quantities of the water weed *Potamogeton* were found, and amongst them what appeared to be diatomaceous frustules. I became suspicious, and my senior officer, Mr. K. D. Downham, had a chemical analysis made of the intestinal contents. A certain percentage of silicon derived from the gizzard contents is always present in the intestine of birds, but in this case was found to be unusually high. A reference to the files showed that in the previous year, 1935, in the same month, and within four days of the then date, another swan had been received from the Gardens with precisely the same lesions. The Gardens were requested to forward a sample of the water and weed from the particular pond, which when received was found to be full of diatoms. The 'weed' consisted largely of filamentous algæ and blades of *Potamogeton*, encrusted with various species of diatom, notably *Fragillaria* and *Gomphonema*. These were also found free-swimming in the water. A chemical analysis of the water alone revealed an abnormally high percentage of colloidal silicon present. (I may here perhaps mention that the analyses were carried out by the analyst of the Harper Adams College, Mr. Lee).

It was therefore assumed that the enteritis in the swan was the result of mechanical irritation caused by the diatom frustules and the free silicon present in the pond.

Freshwater biologists, particularly Kathleen Carpenter in her "Life in Inland Waters", have pointed out that the spring and late winter are the times of maximum diatom increase. Their frustules cause a rise in the silicon content of fresh waters also in autumn, when *Cladocera* feed upon them but release their valves into the water. Birds would be killed in the spring and not in the autumn, because in spring they are greedy for the greenstuff represented by the weeds and because in addition to the diatoms there is present a large amount of free silicon released during the winter by bacterial action, namely, that which the diatoms themselves utilize in the formation of their valves. In autumn, dead shells float freely through the water, and are simply washed through the gut of water-fowl as they swallow water. I suggest that it was because the diatoms were entangled in the weed that they exerted their supposed irritative action; combined with the action of the water saturated with silicon which permeated and enveloped the algal cells.

Instructions were given that the pond was to be drained, all vegetable matter removed and its floor and sides thoroughly scrubbed and disinfected with Chloros; and no further cases have been reported.

Use of Sulphur Dioxide against the Bedbug

SULPHUR dioxide, usually obtained by burning sulphur, when used as a fumigant for bug-infested houses, has not always been successful. Schlupp[1], Gunn[2] and others have suggested that the eggs of the bedbug (*Cimex lectularius* L.) were more resistant than adults to sulphur dioxide. Fetscher[3], however, recorded adults surviving at concentrations which killed the eggs.

I have carried out laboratory experiments to determine the relative resistance of different stages of the bedbug to sulphur dioxide. Using a fumigation apparatus similar to that described by Bovingdon[4], I have exposed different stages of the bedbug for 2½ hours to known concentrations of this gas under controlled conditions of temperature and humidity. A summary of these results, expressed as the amount of sulphur dioxide required to give a complete kill of each stage at 23° C. and 60 per cent relative humidity, is given below.

Stage	Concentration of SO_2 (mgm./litre)	Concentration of SO_2 (% by volume approx.)
0–2 day old eggs	16·7	0·63
2–4 " " "	15·8	0·61
4–6 " " "	12·0	0·46
6–8 " " "	8·9	0·34
1st nymphal instar 1 day after hatching, unfed	6·2	0·23
1st nymphal instar 2 days after feeding	6·1	0·23
2nd " " " " " "	6·0	0·23
3rd " " " " " "	5·7	0·22
4th " " " " " "	5·8	0·22
5th " " " " " "	6·1	0·23
Adults, 2 days after first meal	4·2	0·16

It appears, therefore, that the egg, especially just after being laid, is considerably more resistant to sulphur dioxide than either the adult or any nymphal instar, and that this resistance gradually decreases as the time of hatching approaches.

These results are part of an investigation carried out under the direction of Prof. J. W. Munro on behalf of the Committee on Bedbug Infestation of the Medical Research Council.

Stomatal Movement and Epidermal Water-Content

IN a recent paper, F. J. Nutman[1] has described the behaviour of the stomata of the coffee plant and directed attention to their remarkable sensitiveness to insolation. Within three minutes of exposure to direct sunlight the stomata begin to close, even though the water supply is abundant. Moreover, the closure is reversible: shading a single leaf on an insolated plant results in opening of the stomata of the shaded leaf. This is quite outside the normal range of stomatal behaviour hitherto described.

It seems possible, however, that results obtained in my laboratory by Dr. H. A. Razvi[2] may provide a clue. Following up the observation that the stomata of certain succulents are sensitive to atmospheric humidity, Dr. Razvi discovered that their behaviour, in the leaves of *Kleinia articulata* and *Sedum album*, is not correlated with the water-content of the leaf as a whole, for a turgid leaf in a dry atmosphere will open its stomata less widely than a leaf with a considerable water deficit in a saturated atmosphere.

These observations direct attention to the water content of the *epidermis* as the effective factor. In a dry atmosphere cuticular transpiration, if considerable, would reduce the water-content of the epidermis in relation to the mesophyll. Stomatal transpiration would affect primarily the subepidermal mesophyll and so the epidermis itself. In succulent leaves the vascular organization is not very efficient, and the gradients of water deficit would be correspondingly steep. In a saturated atmosphere, these gradients would be equalized, or possibly the epidermal water-content raised above that of the rest of the leaf by direct absorption, without affecting the total leaf water-content recognizably.

In normal leaves, it is possible that lateral movement of water through the epidermis itself is the main channel of supply to the epidermal cells, direct from the veins. La Rue[3] observed in *Mitchella repens* that the epidermis remains alive and normal even when it becomes entirely separated from the underlying tissues except at the midrib and the margins of the leaf. The wavy outline characteristic of the stomatal epidermis in so many plants must reduce the resistance to lateral passage of water from cell to cell. Freer movement of water through the epidermis would tend towards uniformity of stomatal behaviour.

Since epidermal water-content is the factor directly affecting stomatal movement, and since it may be relatively independent of the water-content of the mesophyll, it is conceivable that insolation of coffee leaves may act by lowering the epidermal water-content although the leaf as a whole remains turgid. The possibility could readily be tested, for the effect should not be observed, or should be reversed, in a saturated atmosphere. Coating the leaf with 'Vaseline' should have a similar effect.

Structure of Permian Homoptera and Psocoptera

THE recent note in NATURE[1] on the ancestors of some groups of existing insects prompts me to mention certain facts apparently overlooked by Prof. G. Zalessky, and to direct attention to others bearing on the subject. Zalessky announces his discovery that the Permian Psocoptera had a "proboscis-shaped" head, provided with a sucking apparatus similar to that of the Homoptera. In 1933[2] I gave a detailed account, which is not mentioned by Zalessky, of the body structure of the Kansan Permian Psocoptera, and demonstrated then (Fig. 13, and plate 1, Fig. 4) that the head possessed a prominent rostrum. The significant feature of the rostrum of these Psocoptera is the presence of large and generalized maxillary and labial palpi, which are scarcely suggestive of the structure of the piercing beak of the Homoptera. Zalessky also states that he doubts the correctness of Dr. R. J. Tillyard's description of the chewing mouth-parts in *Psocidium*. This description I corrected in 1932[3] and at the same time showed *Psocidium* Till. to be a synonym of *Dichentomum* Till., as it was later regarded by Dr. Tillyard[4].

Zalessky also notes his discovery that the members of the order Hemipsocoptera, which was established by him in 1936[5], similarly possessed a "proboscis-shaped" head and mouth-parts like those of the Homoptera. The species for which he erected this new order, *Mauria sylvensis* Zal., was based upon a single and poorly preserved specimen, showing the more general features of both fore and hind wings. At that time (1936) the nature of the hind wings of the Permian Homoptera was not known, and Zalessky, noting that the hind pair of *Mauria* suggested the wings of the Permian Psocoptera, and the fore pair those of the Permian Homoptera (Archescytinidæ), made the new order Hemipsocoptera for the genus. In 1935 I collected in the Permian strata of Kansas a number of Homoptera belonging to several genera of the family Archescytinidæ, descriptions of which are now in press. The hind wings have a venation like that of *Maurii* and the fossils show beyond doubt that the latter is nothing more than a typical member of the Homopterous family Archescytinidæ. It is not surprising, therefore, that the members of the "order" Hemipsocoptera possessed sucking mouth-parts like those of the Homoptera, for as I have already shown (1931)[6], the Archescytinidæ had a perfectly developed haustellate beak, with a swollen clypeal region, and piercing stylets.

The close relationship between the Psocoptera and the Homoptera has been recognized for many years by students of insect phylogeny and morphology, and the similarity between the Permian representatives of these two groups is, of course, very striking. It is unfortunate that Zalessky did not wait for more satisfactorily preserved specimens of *Mauria* before he established a new order.

Points from Foregoing Letters

A NEW type of monochromator, built up of a number of 'Polaroid' films with intermediate quartz plates, is described by Prof. Yngve Öhman, who calculates the intensity of distribution in a spectrum transmitted by such a filter. Single bands of about 50 A. can be separated. Photographs are submitted comparing results obtained with a grating spectrograph and with the new instrument, which appears to be especially useful in observing solar prominences, since the field of view is not limited by a slit as in the ordinary spectrograph.

From X-ray photographs of crystals of ammonia-nickel-nitrate, $Ni(NO_3)_2 . 6NH_3$, S. H. Yü concludes that the behaviour of the NO_3 group in those crystals must be abnormal, and submits diagrams of possible structure which allows for an abnormally large oscillation of the nitrate group. This may be correlated with the large amount of heat motion of the atoms, indicated by the rapid decrease of intensities of the X-ray reflections with increase of glancing angle. Cooling the crystals to the temperature of liquid air produces contraction (at − 100° C.) followed by expansion, while the colour changes from blue-violet to dark purple and then to brilliant pink.

Dr. D. F. Martyn and G. H. Munro have identified a second ordinary echo from the *F* region of the ionosphere at frequencies below the Larmor gyro-frequency $f_1 = He/m$. The retardation of this echo increases, and it eventually disappears just below the frequency $f_1 \cos \theta$, where θ is the complement of the inclination of the earth's magnetic field. The discovery of this echo shows that the Lorentz polarization term is not to be applied in the treatment of dispersion in the ionosphere, and provides a means of measuring the earth's magnetic field in the ionosphere with greater accuracy than was hitherto possible.

Diagrams of transverse sections of the mantle edge of the spat of the oyster before and after attachment are submitted by H. A. Cole. They show in the later stage the existence of a pair of organs not found in the free-swimming larvæ and possibly serving to receive, and react to, vibrations caused by disturbances in the surrounding medium. The newly described sense-organs appear as thin-walled spherical pigmented sacs forming part of the surface layer of cells, projecting from the inside mantle surface and containing, in the cavity, a comparatively large concretion which stains vividly with eosin.

Prof. N. A. Iljin gives an account of experiments in which the shedding of certain types of wool fibres in sheep while other types of wool fibres remain unchanged, is produced by means of treatment with thallium acetate. This phenomenon, termed 'selective or differential experimental moult', is considered as a peculiar morphogenetic reaction; it is evidence of the possibility of a physiological distinction between morphologically different structures proper to the race with a certain genetical constitution.

Prof. H. Munro Fox shows that certain sabellid worms removed from their tubes live indefinitely in aerated water, but they die in water deficient in oxygen, whereas intact worms live in the latter water. In their tubes, these sabellids execute rhythmic respiratory movements, the absence of which in tubeless worms may account for their lower viability. The absence of rhythmic movements in tubeless worms is reflected in their lowered metabolism.

The death of two swans from lesions of the intestine is tentatively ascribed by E. Gray to the presence of diatoms entangled in weeds ingested in early spring, combined with a high percentage of silica in the water.

Prof. D. Thoday directs attention to Dr. Razvi's observation that the opening of the stomata in the leaves of certain succulent plants depends not on the water-content of the leaf as a whole but on the water-content of the surface layer of cells. This, Prof. Thoday suggests, may explain why in the leaves of the coffee plant the stomata begin to close within three minutes of exposure to the sun, though the water supply may be abundant.

Research Items

Identification of Vitamin C

PROF. G. J. COX, in a letter to *Science* (Dec. 10, 1937; p. 540) points out that the award of the Nobel prize for medicine to Prof. A. v. Szent-Gyorgyi (see NATURE, 140, 798; 1937) may tend to obscure the part played by C. G. King and W. A. Waugh, of the University of Pittsburgh, in establishing the identity of vitamin C with a pure crystalline substance. The two groups of investigators, in fact, reached their goal by converging paths, at almost the same time. King and Waugh isolated active crystals from lemon juice and considered the substance to be apparently identical with Szent-Györgyi's "hexuronic acid", and published a note of their results early in 1932 (*Science*, 75, 357; 1932). Svirbely and Szent-Gyorgyi announced, about a fortnight later, that they had protected guinea pigs from scurvy, in an experiment lasting two months, by giving them daily doses of "hexuronic acid" (NATURE, 129, 576; 1932). It must be remembered that the question of the potency of the "hexuronic acid" was not easy to settle, since until it was certain that it had been obtained in the perfectly pure state there was always the possibility to be considered that it was contaminated by another much more highly active substance.

Osmotic Pressure

PROBABLY no conception in physical chemistry is used so often by biologists, with such lack of understanding of its precise nature, as that of osmotic pressure. The so-called pressure is clearly quite fictitious, and corresponds only in very special circumstances to any real pressure. In many quarters, the necessity for a new term to describe the effect is already being felt, and a recent addition to the series "Actualités scientifiques et industrielles" (Duclaux, J., "Pression Osmotique". Traité de Chimie physique appliqué à la Biologie, Tome 2, chap. iv. Paris: Hermann et Cie.) serves to emphasize this view. Although the treatment there is chiefly mathematical, the book is well worth the attention of biologists for its conclusions alone. The original comparison by Van't Hoff with gas pressure, interpreted in terms of the kinetic theory by Nernst, Meyer, Boltzmann, Rayleigh, Kelvin, Gibbs and others, is inadequate in many respects; for attention is concentrated on the solute rather than the solvent, and no account is taken of the two characteristics of osmosis—that the pressure is 'fictitious' and that the volume to be used in the van der Waals equation $PV = RT$ is not the whole volume of the solution. Considerations of the thermodynamical principles involved, made by Van't Hoff, Rayleigh, Gibbs, Planck and others, are equally inadequate, and the various theories they involve would seem to be incompatible. The only satisfactory theoretical expositions of the subject would seem to be those involving the Gouy-Chaperon effect, according to which, in a solution under the influence of gravity, the concentration varies with the height. The chief feature of importance to biologists is the clear recognition that in practice few membranes approach sufficiently closely to the theoretical 'normal' membranes to allow any rigid application of theoretical considerations—in other words, 'abnormal' osmosis in Nature is the rule rather than the exception. One may quote, for example, the fact that the blood of a fish has a concentration lower than that of sea-water, and that urine is more concentrated than blood. In all such cases the equilibrium must be far removed from that of Van't Hoff.

Choice of Background in Fishes

THE colour-change in fishes which takes place when they move from one background to another of different colour has been investigated on several occasions, but not much is known about the possibility of fishes selecting backgrounds to correspond with their skin colour. Observations have been interpreted as yielding positive and negative evidence of choice. Frank A. Brown and David H. Thompson record the results of several thousand choices of individual background-adapted fishes, belonging to eight fresh-water species (*Copeia*, 172; 1937). They reach the definite conclusion that fishes are influenced in their choice by the background to which their skin is adapted. Fishes adapted to black backgrounds choose black more frequently than do fishes adapted to white backgrounds. But in all the eight species tested black-adapted individuals chose black more often than white-adapted chose white. The fishes which showed the greatest modification of background choice as a result of residence upon a black or a white background (silver-mouthed minnow, steel-coloured minnow, straw-coloured minnow, and black-fin) were fishes which frequent shallow and relatively clear water in their natural habitat. The less sensitive were species (orange-spotted sunfish and horned dace) which characteristically hide during a large part of the time.

Larval Characters of the Brachyura

DR. HIROAKI AIKAWA has already advanced considerably our knowledge of the brachyuran larvæ (1933, 1935, 1936) and has devised schemes whereby they may be recognized and classified. In his latest paper "Further Notes on Brachyuran Larvæ" (Records of Oceanographic Works in Japan compiled by the Committee on Pacific Oceanography of the National Research Council of Japan. Tokyo, 1937) he extends these schemes in the light of a large number of new larvæ (30 species) obtained by himself by rearing them from the berried crabs. Taking certain larval characters, especially the second antenna and telson, presence or absence of spines on the carapace, and, in some cases, in addition, the hair formula of the endopodites of the two maxillæ and second maxillipede and the primary chromatophores, he attempts to define the larval characters of the important families including the zoeas of Japanese crabs as well as those of other countries. So great has been the advance in our knowledge of crab zoeas during the last few years that we now know, to a certain extent, the larvæ of 150 species and about 70 genera. Dr. Aikawa has classified all these and gives a key to the families based on larval characters. Applying this also to undetermined zoeas described by various authors, he suggests their probable position. It is interesting that in several cases two megalopæ are found in the life-cycle, whereas certainly in all the British species in which the life-cycle is known there is only one. In *Plagusia dentipes* it is stated that megalopa I stage forms swarms in the open seas from late winter until spring, whilst those of II stage live in great abundance on floating weeds and timbers from spring until early summer.

A Parasite of the Hessian Fly

In the *Journal of Agricultural Research* (55, 199–213; 1937), Messrs. C. C. Hill and W. T. Emery give an account of the biology of the parasitic hymenopteron, *Platygaster herricki*, the host of which is the Hessian fly. In certain parts of the United States, this parasite destroys an appreciable percentage of the fly. Its egg is laid in that of the host, wherein it develops simultaneously with the latter. Development is monoembryonic and not polyembryonic, as in related species of *Platygaster*, and, at the time of hatching, numerous pseudogerms, or groups of trophamnion cells, are liberated into the body cavity of the host. The primary larva at this stage is about 0·29 mm. long: it becomes nearly spherical during growth and gradually consumes the inner contents of the host, but not before the puparium has been formed. When fully fed, the parasite forms a cocoon within the host's puparium. The adult hibernates within the cocoon and emerges in the spring at the time when the Hessian flies are ovipositing. There is only a single generation in the year.

Heart-Rot of Sugar Beet

Sugar beet is subject to a severe disease the symptoms of which are a rotting of portions of the root, and frequently the death of the terminal bud. It is now recognized that this malady is occasioned by a deficiency of boron in the soil. Drs. Winifred E. Brenchley and D. J. Watson have made a study of the effect of this element upon the second year's growth of infected sugar beet (*Ann. App. Biol.*, 24, 3, 494–503, Aug. 1937). Diseased plants from the field were transferred to sand cultures, some of which contained the deficient element in the form of boric acid. Growth made in the absence of boric acid was uniformly diseased, but the addition of this substance in moderate amount (0·25 gm. per 25 lb. of sand) invariably corrected the trouble. Application of a double amount of boric acid, however, had a somewhat toxic effect.

Root Nodules of the Soy Bean

A short account, by Chan Hsien Wu, of the strains of *Bacillus radicicola* from root nodules of the soy bean, is published in the report of the Institute of Scientific Research, Manchoukuo (1, No. 5, 139–162, April 1937). Morphological and cultural characters are described, and the effect of the reaction of the medium upon growth has been investigated. The optimum reaction is about *p*H 6·5, though the organism will grow between the limits *p*H 3·7 and 7·8. Fermentation tests with various polyhydric alcohols, sugars and organic acid salts have been made; mannitol supported the best growth.

Entomogenous Fungi

Mr. T. Petch has continued his "Notes on Entomogenous Fungi" (*Trans. Brit. Mycol. Soc.*, 21, Pts. 1 and 2, 34, Oct. 1937), and provides critical dissertations upon thirty-four species. No fewer than fifteen of these are described for the first time, and thereby attain the dignity of Latin diagnoses. The species belong to a wide variety of genera—*Entomophthora*, *Hypocrella*, *Cordyceps*, *Hirsutella*, *Calonectria*, *Torrubiella*, *Stilbella*, *Isaria*, *Hymenostilbe* and others. The study includes specimens from North America, Ceylon, China, Silesia, Trinidad, Great Britain and many other places the full recital of which would be eloquent of the international scale of Mr. Petch's work.

Fault Lines off Spitsbergen

The recent Norwegian chart of the west coast of Spitsbergen based on extensive echo soundings reveals some submarine features of interest. These are discussed by Dr. O. Holtedahl in *Norsk Geografisk Tidsskrift*, Band 6, Hefte 4, 1936 (republished as *Norges Svalbard og Ishavs-undersökelsr Meddelelse* No. 35). He finds a number of features which resemble closely others found off the coast of northern Norway, especially a longitudinal depression off the coast of Prince Charles Foreland and, more to the east, off the land to north and south. This feature is attributed to longitudinal faults, and these have also been traced in the shelf areas off the coast of Western Greenland. Dr. Holtedahl points to the probability of similar fault lines off Labrador just east of Hamilton Inlet and off Nova Scotia along the inner slope of George's Bank. Similar features may be expected to occur off the west coast of Scotland, although Cainozoic volcanic activity may there have disguised them. Dr. Holtedahl illustrates his paper with a chart of the probable fault line off the west coast of Spitsbergen.

Earthquakes and Atmospheric Pressure

The effects of changes of atmospheric pressure on the occurrence of about two hundred New Zealand earthquakes from 1931 until 1936 are examined by Mr. R. C. Hayes in a brief but interesting paper (*Wellington Dom. Obs. Bull.*, No. 124; 1937). When the pressure rose or fell by one tenth of an inch or more within one or two days before an earthquake, a positive or negative sign was entered at the position of the epicentre. In general, it was found that earthquakes with centres on land were associated with a rise of pressure, and those with centres at sea with a fall, the different signs predominating in series of zones running north-east and south-west, parallel to the main folds and fault-systems of the islands. The most extensive zone is one marked by negative signs lying off the east coast of the North Island, and this is bounded to the north-west by an almost equally well-defined zone on land with positive signs.

Ice Accretion on Aircraft

In Prof. Note No. 82 of the Meteorological Office under the title "Ice Accretion on Aircraft" (London: H.M.S.O.), Sir G. C. Simpson discusses in turn the physics, the meteorology and the practical side of this subject. The physics is a simple matter. We have first the common phenomenon of clouds made up of water drops below the normal freezing point of water and the fact that the latent heat released when such a 'supercooled' drop begins to freeze prevents freezing from being at once completed unless the drop is at least 144° F. below 32° F. The manner of accretion of ice on aircraft is a matter of the size of the drops and of temperature; there are four main types of accretion corresponding with hoar frost, rime, something between rime and glazed frost, and glazed frost. The first may form in clear air when an aeroplane passes from regions of very low temperature into warmer and damper regions and is not thick enough to be very dangerous. The second—rime—comes when the machine flies in clouds made up of very small drops, generally at temperatures many degrees below 32° F. It is a light white deposit on the leading edges of wings, struts, etc., and is dangerous through its alteration of the aerodynamical characteristics of such parts and choking of instruments and carburettor. The third comes in dense clouds made up of large drops more nearly at 32° F. Freezing is very incomplete at impact, and the drops flow for some distance, gradually covering the machine with a dangerously heavy covering of clear ice. Lastly we have glazed frost, which is a similar covering of clear ice, the result of rain from a warmer layer above falling on a machine in a layer with temperature below 32° F. The meteorology of the subject is concerned with the development of rain clouds at suitable temperatures, and is not dealt with in great detail; the practical side is largely concerned with the problem of escaping the dangers of ice accretion either by ascending or descending out of the dangerous layer according to the meteorological circumstances and aided by the wireless warnings issued by the Meteorological Office.

Uranium, Thorium and Lead in Thucholite

THE radioactive carbon mineral thucholite, found in the Parry Sound district, Ontario, has been analysed by O. B. Muench (*J. Amer. Chem. Soc.*, **59**, 2269; 1937). Well-defined crystals, regarded as pseudomorphs after uraninite, were available. The ratio Pb/U was 0·038, whilst that in cyrtolite from the same mine was 0·019. The percentage of uranium in nodular thucholite was almost four times that in the crystalline material, whilst the percentage of thorium was four to five times as great in the crystals as in the nodular mineral. These results indicate a possibility of a concentration of thorium in the crystals and either a leaching of the uranium or else a replacement of the uranium by the carbon mineral. They indicate that Pb/U ratios for this mineral are of little value for an age-determination by this method.

Effect of Temperature on Permanent Magnets

IT has been known for many years that the strength of a permanent magnet changes with alteration of its temperature. In general, the strength diminishes when the temperature is raised and increases when it is lowered. In the case of highly accurate instruments such as electricity meters, the constancy of the strength of the magnets used is of very great importance. It is especially important in the case of the electrical instruments which use permanent magnets employed on aircraft. In view of the recent developments that have been made in the electromagnetic instruments used in high altitude flying where very low temperatures are encountered, it is necessary to know the behaviour of magnets at these temperatures. In a paper by Albert C. Whiffen, published in the December issue of the *Journal of the Institution of Electrical Engineers*, a survey is given of recent researches on this subject. It has been proved that a magnet can be put into the steady condition, as regards magnetic strength, either by mechanical shocks or by cyclic heating. It then has a definite strength at each temperature. A survey of previous experiments shows that the change with temperature depends on the linear dimensions of the magnet. Tests were made of cobalt steel, aluminium-nickel and aluminium-nickel-cobalt alloy magnets over the temperature range from −60° C. to 100° C. An electrically heated oil bath was used for the range 20° C. to 100° C., whilst solid carbon dioxide dissolved in acetone was employed for the range 20° C. to −60° C. It was found that the magnetic strength at any temperature between these limits could be connected with the standard temperature by a quadratic coefficient, both coefficients being negative. It is stated that a magnet which has attained the reversible condition by a series of heating cycles between two limits of temperature is only in the reversible state for these limits of temperature.

Green Flash from Venus

THREE observations of the 'green flash' phenomenon from the planet Venus as it was setting behind a sea horizon are recorded in the meteorological record of S.S. *Tairoa* by Captain W. G. West and W. G. Burt (*Marine Observer*, **15**, 8; 1938). On January 4, 1937, in lat. 1° 00′ S., long. 70° 04′ E., the setting planet, watched through binoculars, turned to a deep green for about half a second before disappearing. On January 5, when the planet was watched through a telescope for five minutes before setting, there were periods of 1–3 or 4 seconds during which the body would appear elongated vertically, with red at the lower limb and green at the upper; the final colour was a dull green. On January 19, when the planet, again watched through a telescope, was only a few minutes of arc above the horizon, a reflection on to the horizon was observed, bright and yellowish in colour. Then "it turned bright red, and as a pillar of red spreading down from the planet to the horizon. After turning back to yellowish-white, it turned green, and then seemed to sink out of sight rather quickly. The whole of this latter phenomenon lasted for not more than 4 seconds."

Most Accurate Method for Determining Meteor Radiants

IN "Extrait, Congrès International des Mathematiciens, Oslo, 1936", Jindrich Svoboda has a paper with the title, "Les Essais expérimentaux du calcul d'un radiant du courant météorique des trajets observés", in which he describes his experiments with a group of artificial meteors. Knowing the true radiant, he used different methods for finding the nearest approach to this, and though the results did not differ very much, one was undoubtedly superior to the others. It was found that when the sum of the squares of the angles by which the lines should be turned around the centre of each trajectory, in order that these lines should pass through the computed radiant, was a minimum, the best results were obtained. Meteor workers may find this conclusion of considerable value.

The Advancement of Science and Society

PROPOSED WORLD ASSOCIATION

AT the recent Indianapolis meeting of the American Association for the Advancement of Science, two important resolutions were adopted unanimously by the Council and may have profound effects, not only upon the future of science, but also upon social history. The resolutions propose, in effect, the setting up of a scientific 'brains trust' for the world, and proclaim the democratic principles of science, and the intellectual freedom of scientific workers; and they denounce totalitarian suppression as a major crime against civilization.

This action may be said to have had its origin in a movement, started several years ago, and strongly supported by NATURE, to make the British Association the platform for the discussion of social problems which science had helped to create and might help to solve. By the time of the Blackpool meeting in 1936, the success of the British Association in this field was manifest. The American delegates, led by Prof. E. G. Conklin, were greatly impressed by the spirit of the meeting. They wanted to hear the men of science of the United States speak as freely, and constructively, on social issues.

Among the American visitors was Mr. Waldemar Kaempffert. Mr. Ritchie Calder, who had already discussed the ideas with leading British men of science, proposed with Mr. Kaempffert 'A Magna Charta of Science'—a declaration of independence, declaring the free, democratic, altruistic principles of science, and also the formation of an Anglo-American concord, as the nucleus of a world organization for all who would subscribe to, and advance, these principles. Together, they saw Prof. Conklin, who wholeheartedly approved, and Sir Josiah Stamp. Coincidentally, Prof. Etienne Gilson, professor of the history of philosophy in the Middle Ages in the Collège de France, was proposing, at the Harvard tercentenary, the setting up of a 'Supreme Court of Science' for the world.

The British Association, during 1937, entered into negotiation with the American Association for collateral membership and exchange of publications, but the major proposals were deferred. In October 1937, however, the *New York Times* published a leading article on an open letter which Mr. Ritchie Calder had addressed, in the *Daily Herald*, to Lord Rayleigh, reviving the proposals. The response in the United States was immediate. Dr. F. R. Moulton, executive secretary of the American Association, made the proposals the basis of his address last December to the Council, in which he also proposed that the American Association should invite lay members, mostly from the universities, to the number of one hundred thousand. The symposium on science and society, Prof. Conklin's inspiring address on science and ethics (see NATURE, Jan. 15), and Dr. Moulton's appeal assured the enthusiastic reception of the proposals. On December 30, the Council of the Association responded by unanimously endorsing the following resolutions:

"Whereas, science and its applications are not only transforming the physical and mental environment of men, but are adding greatly to the complexities of the social, economic and political relations among them; and

"Whereas, science is wholly independent of national boundaries and races and creeds and can flourish permanently only where there is peace and intellectual freedom: now

"Therefore, Be it resolved by the council on this thirtieth day of December 1937, that the American Association for the Advancement of Science makes as one of its objectives an examination of the profound effects of science upon society; and that the Association extends to its prototype, the British Association for the Advancement of Science, and to all other scientific organizations with similar aims throughout the world, an invitation to co-operate, not only in advancing the interests of science, but also in promoting peace among nations and intellectual freedom in order that science may continue to advance and spread more abundantly its benefits to all mankind."

The Association at the same time reaffirmed a resolution on intellectual freedom, originally presented by Dr. Robert A. Millikan and Prof. Henry Norris Russell. The Millikan-Russell resolution, incorporated in the new declaration, reads:

"The American Association for the Advancement of Science feels grave concern over persistent and threatening inroads upon intellectual freedom which have been made in recent times in many parts of the world.

"Our existing liberties have been won through ages of struggle and at enormous cost. If these are lost or seriously impaired there can be no hope of continued progress in science, or justice in Government, of international or domestic peace, or even of lasting material well-being.

"We regard the suppression of independent thought and of its free expression as a major crime against civilization itself. Yet oppression of this sort has been inflicted upon investigators, scholars, teachers and professional men in many ways, whether by government action, administrative coercion or extra-legal violence.

"We feel it our duty to denounce all such actions as intolerable forms of tyranny.

"There can be no compromise on this issue, for even the commonwealth of learning cannot endure 'half slave and half free'. By our life and training as scientists and by our heritage as Americans we must stand for freedom."

As one of the first steps to create the machinery, Dr. Moulton was requested by the council "to take up with the British Association the question of the desirability of inviting its members to join the American Association", so that the combined scientific forces of America and Great Britain should act as a "united world intellect".

Another gesture, which was warmly received by the American men of science, was the announcement made by Sir William Bragg in his presidential address to the Royal Society on November 30 last that the National Academy of Sciences of the United States of America and the Royal Society of London had arranged for the exchange of lectureships between the two democracies in alternate years. An account of this endowment by the Pilgrim Trust was given in NATURE of December 4, 1937 (140, 961).

Geography and Planning

THE Geographical Association's annual conference usually has a theme corresponding to the interests of its president for the time being, and since in its choice of presidents the Association does not confine itself to academic geographers, considerable service to the subject is often done by this importation of a new viewpoint. This year the keynote of the Conference held at the London School of Economics on January 4–6 was the part that geography can play in planning. The presidential address, delivered by Prof. Patrick Abercrombie, professor of town planning at University College, London, was entitled "Geography, the Basis of Planning"; and a symposium on town and rural planning was the principal individual item in the programme. To a certain extent these items in the Conference may be considered as corollary to the important discussion on "Planning the Land of Britain", which was held at the Nottingham meeting of the British Association, as reported in NATURE of November 6, 1937, p. 791.

Prof. Abercrombie took as his starting point the famous Geddes triad "place, work, folk"; geography (place) represents the basis of planning, business (or work) the kernel of planning, and men and women (or folk) the purpose of planning. Planning may be defined as "any conscious effort to mould our environment for our own purposes". The geographer's aid to planning can be given by three types of study: the recording of natural conditions (geology, soil, vegetation, etc.), the tracing of the historic growth of adaptation to environment in the region, and, by combining these two, the presentation of a survey of existing conditions. A plea was put forward for the popularization of geology; the Geological Survey provides ample material in the shape of maps and memoirs, but few people can interpret them without the aid of the professional geologist, and numerous fundamental errors have been made in planning which might have been prevented by a little elementary geological knowledge.

Dr. S. W. Wooldridge, however, in the symposium, contended that the matter is one for geographers; the geologist studies rocks mainly as a record of the earth's history, and is not primarily concerned with the form of the land, and its surface constitution. Both Prof. Abercrombie and Dr. Wooldridge pleaded for soil maps, but had little hope of their appearance for many years. But a more serious handicap is the absence of a complete drift map covering the whole country; the past and present geography of the drift-covered areas cannot be fully appreciated without a map showing the character of the surface deposits.

Dr. Wooldridge said, in addition, that for studying the form of the land something more than contour maps is necessary, and he deplored the abandonment of the fifth (Relief) edition of the Ordnance Survey One-Inch Map—a sentiment which was obviously shared by an audience consisting very largely of school-teachers. Another matter in which the planner must be interested is structure, especially in its effect on water supply. Dr. Wooldridge showed how sub-surface contour maps of water-bearing formations may be far more useful than simple cross-sections; for example, it may be demonstrated that the chalk is much nearer the surface underneath the central part of London than in the regions to the west and east, a fact which has an obvious bearing on the relative difficulty of securing water by boring. He cited cases, too, of buildings which had subsided through being built on a shallow clay formation overlying running sands, and mentioned that central London, built on Thames terrace gravels, is the only part that has subsided appreciably, the parts built on London Clay showing no movement. He added a warning that the expansion of 'bungaloid growths' on the top of the chalk dip-slope around London may have disastrous effects on the pollution of the water, which runs down the dip to the areas from which well-water is obtained.

Both Prof. Abercrombie and Dr. Willatts were concerned with agriculture, which the former called the "Cinderella of planning". There is a well-known phrase "an army moves on its stomach"; it is equally true that the non-combatants must be fed in time of war, and in an island country such as Great Britain, it seems curious that so much attention should be given to the production of weapons of defence and aggression, and so little to the possibility of making the nation more self-supporting in essential foodstuffs. Agriculture, in the law, is not regarded as a development at all; 'development' consists of the utilization of the land for building purposes, and planning schemes plan the extension of urban areas, not the extension, nor even the retention, of agricultural land-use. The land, as Dr. Stamp said at Nottingham, is our one ultimate asset; the soil is a form of capital; yet not only have three-quarters of a million acres of farm-land been lost to the nation since 1900, but also, by a curious misfortune, it is usually the best agricultural land which is taken for building.

Dr. Willatts, who is organizing secretary of the Land Utilization Survey, stressed the need for a historical study of land utilization. The present use represents the result of centuries of adaptation; modern planning visualizes a sudden change. Only by studying the past land uses can apprisal be made of the optimum use of any given area. Thus near London there are three large areas of rich market-garden land—actually amongst the finest soils in the country, in western Middlesex, south-west Essex and north-west Kent—all of which are being rapidly eaten into by the builder. No account whatever seems to have been taken of the agricultural value of this land, either in planned or haphazard development. It is noteworthy that London's open heaths (for example, Hampstead, Wimbledon) have remained as such for centuries because of poverty of soil; they would make admirable residential areas, yet what an outcry there would be if they were to be built on! But thousands of acres of rich arable land, which for centuries has yielded abundant harvests to the farmer or small-holder, are now being destroyed by houses and factories without a protest being raised. The 'gravel subsoil' of the Thames terraces is far more valuable to the builder as an inducement to the prospective purchaser than the poorer clay land, and could far better be spared from the rapidly decreasing area of farm land. The question which the geographer, and the planner, may ask is, "Which is the best and most economic use of this land, considered from the national point of view—for houses or crops ?"

Lastly, Dr. R. A. Pelham urged a better appreciation of traditional building styles and materials in the development particularly of rural areas, in order that such "incongruous atrocities" as rows of red brick houses on the edge of Cotswold towns and villages might be avoided. It is feared, however, that this is an age in which utility and cheapness are more often considered than the æsthetic, and it is after all much cheaper and easier to build with mass-produced bricks than with elaborately prepared stone.

Apart from a highly entertaining and unbiased lantern lecture on South Russia and the Caucasus by Sir John Russell, and a fascinating biological introduction to the study of landscape from Prof. H. H. Swinnerton, the remaining items in the Conference dealt mainly with educational subjects, ranging from the conception of geographical ideas by school-children to the conception of examination questions by examiners, and from the study of local geography by observation to the study of far-off lands by corresponding with the officers of 'tramp' ships. A lengthy report of a committee of the Association which has been studying world natural regions was also submitted and discussed; the report has been published in full in the December 1937 issue of *Geography*. S. H. BEAVER.

Prize Awards for 1937 of the Paris Academy of Sciences

AT the annual public meeting held on December 20 last the president announced the prizes and grants awarded in 1937 as follows :

Mathematics. The Francœur Prize to Jean Leray, for his work on mathematical analysis.

Mechanics. The Montyon Prize to Lucien Malavard, for his electrical apparatus for the rapid calculation of the distribution of hydrodynamic circulations. The Poncelet Prize to Joseph Bethenod, for his work on mechanics and electricity. The Pierson-Perrin Prize to Léon Brillouin, for the whole of his work, especially for his contributions to the development of quantum mechanics.

Astronomy. The Lalande Prize to Michel Giacobini, for his work on stellar astronomy and comets. The Benjamin Valz Prize to Maurice Burgaud, for his work on terrestrial magnetism in China. The G. de Pontecoulant Prize to Henri Roure, for his work on planetary perturbations.

Geography. The Gay Prize to Jean Vignal, for his work on the accuracy of a method of levelling. The Tchihatchef Prize to Etienne Bruzon, for his travels, work and publications relating to the climate of Indo-China. The Binoux Prize to Raoul Goudey and Jean Lagrula, for their gravimetric observations made in France and Northern Africa. The Alexandre Givry Prize to Henri Legrand, for the whole of his hydrographical work in France and its colonies.

Navigation. The Plumey Prize to Roger Brard, for his studies on screw propellers.

Physics. The Kastner-Boursault Prize to Bernard Decaux, for his work on the applications of piezoelectric quartz to chronometry. The Gaston Planté Prize to Jean Bernamont, for his studies on the fluctuations of electrical resistances. The François Hébert Prize to Paul Couderc, for his work on astronomy. The Henri de Parville Prize to Paul Lainé, for his researches on the magnetic and magneto-optic properties of liquefied gases. The Hughes Prize to Paul Soleillet, for his work on the structure of light. The Clément-Félix Foundation to Etienne Vassy, for his work on atmospheric ozone.

Chemistry. The Montyon Prize (Unhealthy Trades) to Roger Renaud, for his work on gas masks. The Jecker Prize to Gustave Vavon, for his work on catalytic hydrogenation and the stereochemistry of the cyclic compounds. The Cahours Foundation to Georges Laude, for his work on the synthesis of cyanic acid. The Paul Marguerite de la Charlonie Prize to Georges Darzens, for his work in organic chemistry. The Berthelot Prize to Jacques Parrod, for his researches on the synthesis of hydrocyanic acid. The Houzeau Prize to Marius Picon, for his work on sulphides and camphocarbonates. The Charles Adam Girard Foundation to Georges Brooks, for his researches in biological chemistry.

Mineralogy and Geology. The Delesse Prize to Mlle. Simonne Caillère, for her work on the minerals of the serpentine group. The Victor Raulin Prize to Mlle. Henriette Alimen, for her studies on the Stampian of the Paris basin.

Botany. The Desmazières Prize to Robert Potier de La Varde, for his work entitled "Mousses du Gabon". The Montagne Prize to Marius Chadefaud, for his work on Algæ. The Jean Thore Prize to Emile Chemin, for his biological researches on certain Algæ. The de la Fons Mélicocq Prize to Maurice Bouly de Lesdain, for his work entitled "Graminées indigènes et adventices des environs de Dunkerque". The de Coincy Prize to Raymond Benoist, for work in systematic botany in tropical regions.

Anatomy and Zoology. The Cuvier Prize to Paul Chabanaud, for the whole of his work. The Savigny Foundation to Henri Heim de Balsac, for his book on the mammals and birds of northern Africa.

Medicine and Surgery. Montyon Prizes to Emile Césari and Paul Boquet (2,500 francs), for their researches on the antigens of snake poisons and the antibodies of the sera ; Michel Salmon (2,500 francs), for his book on the arteries of the skin ; Jean Vague (2,500 francs), for his book "Les Hépatonephrites aiguës". Honorable Mentions (1,500 francs) to Ram Kumar Goyal, for his contribution to the study of the Streptothriceæ ; to Eugène Saint-Jacques, for his work on injections of animal charcoal in various diseases ; and to Jean Terracol, for his book on the diseases of the nasal fossa. The Barbier Prize to P. Emile Weil, Paul Isch Wall and Mme. Suzanne Perlès, for their book on the puncture of the spleen. The Bréant Prize to Georges Girard and Jean Robic, for their work on the application to man of a new vaccine against plague. The Godard Prize to Gaston Gros, for his memoir on sexual endocrinology. The Mège Prize to Georges Curasson, for his treatise on veterinary pathology. The Bellion Prize to Jacques Vialle, Chevalier Jackson and Chevalier L. Jackson, for their memoir on bronchoscopy in bronchopulmonary affections. The Argut Prize to Jean Braine and Raymond Rivoire, for their book on the surgery of the parathyroid glands. The Charles Bouchard Foundation to Maurice Doladilhe, for his studies on the properties of the blood serum. The Jean Dagnan-Bouveret Prize to Michel Weinberg, for his memoir on the anærobic micro-organisms.

Cancer and Tuberculosis. The Roy-Vaucouloux Foundation to Eugene Wollman, for his work on the nature of malignant tumours. The Louise Darracq Prize to Mme. Nadine Dobrovolskaia-Zavadskaia, for work on cancer. The Henriette Régnier Foundation to Robert Broca, for work on tuberculosis.

Physiology. The Montyon Prize to Mlle. Eliane Le Breton, for her memoir on the physiological signification of the oxidation of ethyl alcohol in the organism. The Pourat Prize to Georges Morin, for his work on the intestinal automatism of the vertebrates and its regulation. The Philipeaux Prize to Jean Roche, for his physiological and biological researches on the respiratory pigments. The Fanny Emden Prize between André Tournade (2,000 francs), for researches in experimental physiology, and Raoul Lecoq (1,000 francs), for researches on the B vitamins.

Statistics. Montyon Prizes to Mlle. Dagmare Weinberg (1,000 francs), for her work on the correction of examination papers ; Adolphe Lesage and Marcel Moine (1,000 francs), for their study on infant mortality during the first year. A Mention (500 francs) to Marcel Luc-Vernon, for his studies on the science of values applied to bookkeeping and the statistics of undertakings.

History and Philosophy of Science. The Binoux Prize to Cornelis de Waard, for his contribution to the edition of the correspondence of Père Marin Mersenne.

Works of Science. The Henri de Parville Prize to the Association de la Presse de l'Institut et des Sociétés Savantes.

Medals. The Berthelot Medal to Roger Renaud and to Jacques Parrod.

General Prizes. The Prize founded by the State to Gaston Delépine, for the whole of his palæontological and geological work. The Alhumbert Prize to (the late) Fernand Jacquet, for his researches on the stratigraphy of Senegal and Mauritania. The Bordin Prize to Georges Darmois, for his work on the calculus of probabilities. The Lallemand Prize to Jean Delay, for his work entitled "Les Astéréognosies. Pathologie du toucher". The Petit d'Ormoy Prize (Mathematical Sciences) to Paul Lévy, for the whole of his mathematical work, (Natural Sciences) to Emile Roubaud, for the whole of his entomological and biological work. The Saintour Prize to André Marchaud, for his work on geometry. The Lonchampt Prize to Lazare Silberstein, for the whole of his work on the importance of sulphur in plants and animals. The Wilde Prize to René Lucas, for his work on transversal waves in liquids. The Gustave Roux Prize to Stanislas Goldsztaub, for his work on the crystalline structure of the natural hydrated iron oxides. The Thorlet Prize to Paul Dorveaux. The Marquet Prize to Charles Joyeux, for the whole of his helminthological studies. The Général Muteau Prize to Gaston Ramon, for work on the anatoxins.

Prizes of the Grand Ecoles. The Laplace Prize to Charles Crussard. The L. E. Rivot Prize to Charles Crussard, Jean Hüe de la Colombe, André Brocard and Bruno Cirilli.

General Foundations for Scientific Research. The Gegner Foundation to Claudius Roux, for his work on natural science and the history of science. The Hirn Foundation to Marcel Fouché, for his work in acoustics. The Henri Becquerel Foundation to André Savornin, for his work in terrestrial magnetism.

THE LOUTREUIL FOUNDATION

Researches on Fixed Questions. Henri Erhart (5,000 francs), for the extension of his pedological researches. Albert Henry (3,000 francs), for his researches on parasitism of the mammary gland. Louis Nattan-Larrier (6,000 francs), for the study of the serological conditions of the development of normal tissues and of cancers. Paul Vayssière (3,000 francs), for work on the disinfection and preservation of agricultural products.

Researches to be Carried out in French Colonies. Lucien Berland (8,000 francs), for researches on the entomological fauna of the upper regions of the atmosphere, especially in Senegal. Henri Humbert (6,000 francs), as a contribution to a new botanical expedition in southern tropical Africa and in the north-west of Madagascar.

For Laboratory Equipment. Zéphirin Carrière (10,000 francs), for the purchase of an electrical apparatus for the analysis of sound. Institut national agronomique (10,000 francs), for the purchase of a microscope for the examination of fluorescence by production of ultra-violet rays. Casimir Monteil (5,000 francs), for the purchase of a petrol motor for brake measurements. Henri Thiel (2,000 francs), for the purchase of a Nistri stereographometer.

Publications. Comité de Physique du Globe des Colonies (10,000 francs), for the publication of the "Annales de Physique du Globe de la France d'outremer". Fédération française des sociétés de sciences naturelles (4,000 francs), for the publication of the "Fauna de France". Henri Gaussen (5,000 francs), for the publication of a memoir by Charles Flahault on the flora of the French Mediterranean region. Marc Simonet (4,000 francs), for the publication of sixteen coloured plates of certain hybrids of *Iris*. Société Linnéenne de Lyon (3,000 francs), for the publication of library catalogues.

Libraries. Ecole nationale vétérinaire d'Alfort (8,000 francs), for preparing a card catalogue and completing its foreign periodicals. Ecole nationale vétérinaire de Lyon (7,000 francs), for the purchase of foreign veterinary works. Ecole nationale vétérinaire de Toulouse (7,000 francs), for the purchase of French and foreign veterinary works. Ecole polytechnique (5,000 francs), for the purchase of scientific publications. Institut national agronomique (5,000 francs), for the purchase of foreign periodicals. Société astronomique de France (2,000 francs), for increasing its collection of lantern slides. Société d'encouragement pour l'industrie nationale (8,000 francs), for the purchase of foreign works.

MME. VICTOR NOURY FOUNDATION

Edgar Aubert de La Rue, for his explorations in the French Colonies ; Albert Berthelot, for the whole of his studies ; Maurice Bouvet, for his work on the history of pharmacy in France ; Gilbert Ranson, for his memoir on the medusæ collected during the voyages of Prince Albert I of Monaco ; Constantin Toumanoff, for his studies relating to antipaludism in Asia (2,500 francs each).

GENERAL FOUNDATIONS

The Henry Le Chatelier Foundation to Léon Guillet, for his studies on zirconium and beryllium. The Millet-Ronssin Foundation to Justin Savornin (4,000 francs), for his geological work in Algeria; Paul Remy (3,000 francs), for the whole of his zoological work and especially that on insects; Robert Kühner (3,000 francs), for his researches on Basidiomycetes.

VILLEMOT FOUNDATION

Mme. Rose Bonnet-Sainturier (15,000 francs), for the publication of a memoir on the double stars. Lucien Cayeux (15,000 francs), for the purchase of a polarizing microscope and various other instruments. Aimé Cotton (40,000 francs), for the electromagnet laboratory. Alexandre Dauvillier (12,000 francs), for a recording electrometer. Jean Goarnisson (5,000 francs), for the establishment of a laboratory for the preparation of certain remedies against leprosy and sleeping sickness. Edouard Legé (53,000 francs), for experimenting, on a semi-industrial scale, on the synthetic preparation of motor petrol from certain colonial seeds. Charles Maurain (15,000 francs), for researches on terrestrial magnetism and atmospheric electricity. Marin Molliard (5,000 francs), for researches on the morphogenic and physiological action on plants of atmospheric gases under varying pressures. Albert Peyron (8,000 francs), for the development and publication of his studies in comparative pathology relating to tumours. Maurice Piettre (10,000 francs), for the installation of a low-temperature room at the Halles. Gustave Ribaud (10,000 francs), for the experimental study by various methods of the heat losses through the walls of furnaces. Hyacinthe Vincent (12,000 francs), for the purchase of laboratory animals and material for continuing his researches on immunity and pathology of infectious diseases.

SPECIAL FOUNDATIONS

The Lannelongue Foundation to Mme. Gabriel Cusco. The Girbal-Baral Foundation (each 10,000 francs) to Daniel Bouttier and Julien Jouin. The d'Aumale Prize Grants of 5,000 francs each to the widows of Joannès Chatin and Jean Charcot.

Science News a Century Ago

Russian North Polar Expeditions

UNDER the above title, the *Athenæum* of January 27 gave a long account of the exploration of the coasts of Novaya Zemlya based on the memoirs of von Baer contributed to the Imperial Academy of Sciences, St. Petersburg. After referring to the earliest voyages to the north, the writer of the review said: "During the years 1819–24 five well equipped expeditions were despatched by the Russian government for the Survey of Novaïa Semlïa, four of which were under the command of the experienced navigator Lütke; yet they all failed in the especial object of their mission, namely, to trace the eastern coasts of that country." In 1832 a merchant of Archangel named Brandt, equally alive to the interests of science and of commerce, formed a company, and despatched one ship commanded by Lieut. Krotoff to sail along the west coast of the islands and a second in command of the pilot Pachtussoff to survey the eastern coasts. A third vessel sent to the western coast in search of walrus returned richly laden. Lieut. Krotoff and his ship were lost, but Pachtussoff and his party wintered in the north and made valuable surveys.

In 1834 the Russian Government fitted out two vessels, one commanded by Pachtussoff and another by Ziwolka. Leaving Archangel in July, Pachtussoff was away about a year and died shortly after his return. "The two expeditions conducted by Pachtussoff," said the *Athenæum*, "produced a mass of meteorological observations of a very valuable kind, and which bear unequivocal testimony to the carefulness and assiduity of that officer." The greatest cold experienced in Novaya Zemlya was in February, when the thermometer fell to − 40°. It often remained for days together at −34°.

Karl Ernst von Baer was born in Esthonia on February 17, 1792, and studied medicine at Dorpat. Finding that his native country presented indifferent prospects for a naturalist, he went to Germany and became professor of zoology at Könisberg, where he founded a Zoological Museum. In 1834 he was appointed librarian to the Imperial Academy of Sciences, in which situation he made use of his opportunities to collect information regarding the polar regions of the Russian Empire. He had previous to this become famous for his discovery of the mammalian ovum, which led to his being regarded as the founder of comparative embryology. His death took place at Dorpat on November 28, 1876.

The Zoological Society

AT a meeting of the Zoological Society held on January 23, 1838, Richard Owen being in the chair, Mr. Ogilby characterized several new species of mammals contained in the collection made by Captain Alexander in South Africa, and Mr. Gould described several new and interesting birds included in the collection. Among them was an eagle with a white breast and red tail; two small falcons, scarcely exceeding in size the English house-sparrow; and a very small owl of scarcely larger size. There was also a jay of very gaudy plumage which perches upon the horns of rhinoceros, supposedly for the purpose of obtaining insects; the hunters of the rhinoceros anxiously watch this bird, as when they see it fly up from the horn they know that the animal is alarmed. At the same meeting, Owen read some observations on the anatomy of the giraffe, from dissections made of the animals which died at the Regent's Park and Surrey Zoological Gardens.

The Morse Telegraph

"A NEW and improved transmitting and recording apparatus was completed for Prof. Morse by his partner, Mr. Alfred Vail, of the Speedwell Iron-works, near Morristown, N.J., at the close of the year 1837; and early in January, 1838, Prof. Morse first discarded the numeral signs for words, and employed a true *alphabet* of 'dots and dashes'. The first exhibition of an alphabetic record of words and sentences took place in the New York City University, on January 24, 1838, through ten miles of wire wound on reels. The New York *Journal of Commerce*, in a notice of this performance, remarked, 'Professor Morse has recently improved on his mode of marking, by which he can dispense altogether with the telegraphic dictionary, using letters instead of numbers'." ("A Memorial of Joseph Henry", p. 384.)

Societies and Academies

Paris

Academy of Sciences, December 6 (*C.R.*, 205, 1113–1188).

Dimitri Riabouchinsky : Hypersonic waves in gases.

Lucien Daniel : New researches on the variations of the reserve function in the autonomous and grafted Jerusalem artichoke.

Lucien Hibbert : Univalence cells of polynomials.

Amédée Guillet : The determination of a network of values of the acceleration of gravity (g) centred on a given station.

Alexandre Favre : The experimental study of movements in two dimensions by means of the Toussaint-Carafoli hydrodynamic tunnel : the influence of the viscosity.

Emile Merlin : A theorem on the motion of fluids deprived of acceleration.

G. A. Mokrzycki and J. Wysocki : *Décollage* in flight.

Jean Hély : A synthetic theory of gravitation and of electromagnetism.

Gérard Petiau : A system of hypercomplex numbers derived from the system of quaternions.

Jean Roubaud-Valette : The passage of vectorial magnitudes to the corresponding spinors by the notion of sub-spaces. The interpretation of Dirac's equations.

Gustave Robaud : The calculation of the temperatures and pressures in a closed vessel. The use of a QT diagram, where Q is the total heat necessary for the partial dissociation of the CO_2 and O_2 molecules and to carry the products of dissociation from the temperature T_0 to T, simplifies the laborious calculations hitherto necessary.

Georges Simon and Jean Bouchard : The influence of a longitudinal magnetic field on the thermo-electric power of nickel and of various ferronickels submitted to traction.

V. Dolejšek and M. Tayerle : The separating power in X-ray spectra.

Maurice Cotte : Aberrations of the second order of orthogonal systems.

Claude Magnan : Study of the energies of electrons and positrons emitted during certain nuclear reactions.

Augustin Boutaric : Some simple formulæ relating to adsorption phenomena occurring in mixtures.

Wilfried Heller and Mlle. Germaine Quimfe : The isothermal and reversible immobilization of the particles in thixotropic sols.

Paul Mondain Monval : The application of the laws of displacement of equilibrium to heterogeneous liquid mixtures.

Emile Carrière and Maurice Delpla : The comparative action of potassium iodate and of potassium periodate on sodium thiosulphate in weakly acid medium. The oxidation of sodium thiosulphate by iodic acid is markedly influenced by the hydrogen ion concentration, but with periodic acid this concentration has small influence.

Maurice Anglade : The synthesis of the mono-ether oxides of 2,4-dimethylolanisol.

Antoine Hautot : A method of measuring the periodic internal potential of crystals.

Fernand Jacquet and Maurice Nicklès : The relations of the eastern Senegal chain with the Mauritanian and Sudanese plateaux.

Jean Marçais : The tectonic constitution of the eastern French Rif.

Albert Robaux and Marc Bernatzky : The tectonic of the secondary strata of Lorraine.

Octave Mengel : The Robinet of Donzère : its relations with the physiography and seismicity of the Tricastin (Drôme).

B. Trouvelot and G. Busnel : Modifications of the rhythm of the cardiac beats in the larvæ of Doryphora (*Leptinotarsa decemlineata*) produced by the *Solanum* on which they are feeding.

Pierre Drach : The morphogenesis of the external crystalline mosaic in the tegumentary skeleton of the brachyurous Decapods.

Albert Guieysse-Pellissier : The pulmonary vessels with striated fibres of the small mammals.

René Guy Busnel : The biochemical study of the lipins and reducing substances in *Leptinotarsa decemlineata*.

René Couteaux : Origin of the secondary myotubes in the embryos of mammals.

Serge Tchakhotine : An arrangement (drops of water in a non-miscible liquid) for researches in embryology and experimental cytology.

Henri Nouvel : Observation of coition in a species of Mysis, *Praunus flexuosus*.

Auguste Trillat and Arthur Beauvillain : An attempt at the aerial transmission of influenza to the ferret through the lungs or eyes.

Moscow

Academy of Sciences (*C.R.*, 16, No. 9 ; 1937).

N. Vedenisov : Varieties of E. Čech.

G. N. Neujmin : Return to perihelion of the periodical comet Neujmin II in 1937.

J. Larionov and A. Seidel : Photo-luminescence of solutions of rare earth salts.

H. Neujmin : Use of solid indicators for direct detection of photo-dissociation products.

A. E. Porai-Koschitz and A. I. Kulikov : A new substantive colouring matter.

A. E. Porai-Koschitz, B. A. Porai-Koschitz and S. A. Luick : Constitution of chinophtalon.

L. S. Selivanov : Composition of the mud of the brine of the Karabugaz Gulf.

D. F. Petrov and D. A. Tukan : Heterozygoty of the male sex in *Fragaria orientalis* Los.

K. E. Ovčarov : Production of thiourea by fungi.

I. A. Stefanovskij and I. V. Guščin : Specific action of drought on wheat crops at various stages of development.

T. A. Krassnoselskaja-Maximova, T. V. Kulagina, K. I. Orlova, L. N. Filimonova and N. V. Cugrejeva : Physiology of apple trees in relation to soil conditions.

A. Jacenko-Chmelevskij : Some peculiarities in the conductive system of the petiole of ramie (*Boehmeria nivea*, var. *tenacissima* Gaudich).

M. F. Nikitenko : Problem of the mechanism of regeneration of the eye lens in Amphibia.

C.R., 17, Nos. 1–2 ; 1937.

M. M. Greenblum : The adjoint transformation.

D. A. Frank-Kameneckij : The limiting form of the free convection law for high values of Grasshof's criterion.

K. Alexeeva : Artificial radioactivity of antimony provoked by slow neutrons.

G. V. Gorškov and V. N. Ionov : A new method of determining radium, mesothorium I and radiothorium in sealed preparations.

S. J. Turlygin: Effect of electromagnetic centimetre waves on the central nervous system.

A. A. Grünberg and P. M. Filinov: The hydroxy compounds of quadrivalent platinum (1).

I. Preobraženskij: Tin-bearing granitoids of Borshchovochny Range, Eastern Transbaikalia.

V. V. Aršinov: The pocket mineralogical or polarizing magnifier.

K. L. Povolockaja: Vitamin C in germinating seeds.

A. G. Šestakov and A. P. Kačeev: Method of rapid determinations of chlorine in plants.

M. F. Ternovskij, M. I. Khmura and N. I. Zhukov: Inheritance of nicotine and anabasin in inter-specific hybrids with *Nicotiana glauca* Jr.

V. V. Butkevič: Soil temperature and the effect of fertilizers on the yield and quality of spring wheat.

M. M. Gogolašvili and N. A. Maximov: Effect of heteroauxin in the rooting of cuttings from subtropical wood.

A. Sereiskij and M. Sludskaja: Acceleration of the growth of seedlings and the accumulation of blastanin in the endosperm through the vernalization of spring and winter wheats.

T. T. Demidenko and V. P. Popov: Periods of absorption of nutrient substances by the sunflower plant in connexion with supplementary feeding.

V. P. Popov: (1) Influence of daily introductions of nitrogen and phosphorus on the storing-up of hydrophilic colloids in sugar beet. (2) Colloidal chemical composition of sugar beet as determined by the time of introduction of nutrient substances.

M. S. Jakovlev: The number of fibro-vascular bundles in the coleoptile of barley and oat.

K. T. Sukhorukov and O. B. Nataljina: The harmfulness of anthracnose of black currant.

I. Švajkovskij: Aerodynamic properties of insects.

A. A. Voitkevič: Morphogenetic activity of different parts of the hypophysis. (7) The growth-stimulating influence of the "eosinophilous zone" of anterior lobes of the hypophysis, and of other endocrine organs.

G. V. Boldovskij: Warm-water Euphausiidæ (Crustacea) of the Murman coast.

Tokyo

Imperial Academy (*Proc.*, **13**, No. 8, 1937).

Motokiti Kondô: Standardization of complementary analytics.

Sôichi Kakeya: Boundary values of analytic functions.

Sôichi Kakeya and Kinjiro Kunugi: A relation between the length of a plane curve and angles stretched by it.

Kôsaku Yosida: The exponential formula in the metrical complete ring.

Tetsuro Ikeda: Wearing of the micrometer screw of the Wanschaff zenith telescope. The wearing of the screw is due to the repelling force of the spring.

Mankiti Hasegawa and Yûiti Tamura: The regular progressive changes of the magnetic field in diurnal variations of terrestrial magnetism (1).

Shinkichi Yoshimura: Abnormal thermal stratifications of inland lakes. Three kinds of chemical stratifications are designated: (*a*) biochemical; (*b*) non-biochemical; (*c*) combined stratifications of biochemical and non-biochemical origin.

Rempei Goto: Positive ion emission from heated nickel wire in oxygen and hydrogen. Oxidized nickel wire heated in oxygen or hydrogen emits some positive ions.

Teikichi Fukushi: An insect vector of the dwarf disease of the rice plant. Another species of leafhopper, *Deltocephalus dorsalis* Motsch., is shown to be a vector of the disease.

Tsuneo Eguchi: Effects of the length of day upon time of differentiation of the flower bud and the subsequent development to flowering.

Forthcoming Events

[*Meeting marked with an asterisk is open to the public.*]

Monday, January 24

Engineers' Study Group on Economics (at 64 Great Cumberland Place, W.1), at 8.—Alexander Farquharson: "Frederick Le Play, Engineer and Sociologist".*

Royal Geographical Society, at 8.30.—Dr. C. von Furer-Haimendorf: "Journeys in the Naga Hills, Assam".

Thursday, January 27

Royal Society, at 4.30 p.m.—E. Gluckauf and Prof. F. A. Paneth: "Identification and Measurement of Helium formed in Beryllium by Gamma Rays".

J. W. J. Fay, E. Gluckauf and Prof. F. A. Paneth: "On the Occurrence of Helium in Beryls".

The Chemical Society (at the London School of Hygiene and Tropical Medicine), at 5.30.—Prof. Richard Kuhn: "Synthesis of Polyenes" (Pedler Lecture).

Friday, January 28

Geophysical Discussion (at the Royal Astronomical Society), at 4.30.—"The Montserrat Expedition" (Opener: Dr. C. F. Powell).

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Junior Scientific Officer at the Building Research Station, Garston—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (January 25. Quote J. 38/1).

Lecturer in Electrical Engineering in the Wolverhampton and Staffordshire Technical College—The Director of Education, North Street, Wolverhampton (January 27).

Heads of the Science and Engineering Departments of the South-West Essex Technical College—The Director of Education, County Offices, Chelmsford (January 31).

Assistant Lecturer in Entomology in the School of Tropical Medicine, Pembroke Place, Liverpool, 3—The Secretary (January 31)

Chief Physicist, an Applied Physicist, and a Colour Chemist to the Wool Industries Research Association, Torridon, Leeds, 6 (January 31).

Deputy Director of the Imperial Bureau of Dairy Science—Prof. H. D. Kay, National Institute for Research in Dairying, Shinfield, Reading (February 5).

Mycologist in the Plant Pathological Laboratory, Harpenden—The Secretary, Agricultural Research Council, 6A Dean's Yard Westminster, S W.1 (February 7).

Assistant Keeper in the Science Museum—The Director of the Science Museum, South Kensington, S.W 7 (February 14).

Chemist in the Geological Survey Department, Federated Malay States—The Director of Recruitment (Colonial Service), 8 Buckingham Gate, Westminster, S W.1 (February 15).

Scientific Assistant (veterinary) at the Field Station, Compton, Berkshire—The Secretary, Agricultural Research Council, 6A Dean's Yard, Westminster, S.W.1 (March 1).

James Watt Professor of Theory and Practice of Heat Engines in the University of Glasgow—The Secretary (March 1).

Civil Engineers in H.M. Naval Establishments—The Civil Engineer-in-Chief, Admiralty, S.W.1.

Abstractor from the Slavonic Languages at the Imperial Mycological Institute, Ferry Lane, Kew, Surrey—The Director.

Veterinary Research Officer in Palestine—The Director of Recruitment (Colonial Services), Colonial Office, 8 Buckingham Gate, S.W.1.

Ethnographical Museums and Empire

IN a lecture delivered recently before a joint meeting of the Royal Society of Arts and the India Society by Mr. J. de La Valette (*see* NATURE, Dec. 25, p. 1108) attention was directed to the work of the museums of Holland in promoting the study of the indigenous cultures of the Dutch possessions in Indonesia, and their aim of making familiar to the Dutch people the conditions of native life in these remote parts of the world, for the administration of which they themselves are ultimately responsible. In its broader aspect the problem with which those who have organized these museums have been confronted is one obviously of special interest to Great Britain, where there is a like need for general understanding of alien peoples and cultures under one and the same ***imperium***, but on a vastly extended scale.

Mr. de La Valette pointed out that in their method of approach to the problem of the arrangement and organization of an ethnographical museum demonstrating the mode of life of their dependencies, the Dutch are in harmony with the modern tendency towards a 'humanism' in anthropological studies, in which the various disciplines of the study of man—ethnology, physical anthropology, archæology, history and the like—set apart for academic purposes in the past, are once more brought together and focused on the study of a single integrated group or culture. Man, his works and his environment, are thus studied as a single and unified whole and not in water-tight compartments. Mr. de La Valette then went on to contrast with these methods the antiquated procedure, as he sees it, of the museums of Great Britain; he admitted that they are unrivalled in the extent and variety of their collections, but, he maintained, dominated by a Victorian tradition of specimen-collecting and a passion for classificatory arrangement, which sterilizes them of all life and meaning in relation to the cultural history of man in its specific manifestations.

In directing attention to the merits of this regional or unitary method of museum organization in ethnographical studies, in which the whole life of a group is displayed as a rounded whole, Mr. de La Valette raised a question to which in its wide ramifications it is difficult to set limits of discussion. He was also in the strong tactical position of addressing an audience the interests of which in the main were directed to a single area, India—which is none the less concentrated though it is a sub-continent comprising not one but many ethnic, cultural and regional units. On the general question, however, this much may be said. In so far as the aim of the Dutch museums has been to bring home to their people an understanding of the life of their subject populations by intensive illustration, it is in accord with anthropological opinion in Great Britain, where the advantage to the British people of an ethnographical museum demonstrating the life and modes of thought of the peoples of alien culture of the dominions and dependencies has long been urged. Close on forty years ago Mr. (later Sir) Hercules Read, keeper of the Ethnographical Department of the British Museum, advocated in the strongest terms the establishment of an Imperial Bureau of Anthropology in connexion with his department, and time and again since then the need of an imperial ethnographical museum has been urged as the best, if perhaps not the only, means of promoting an educated interest among the general public in our dependent and fellow-subjects of culture other than our own.

While it is probable that there would be no two opinions as to the desirability, not to say the urgency, of establishing an imperial ethnographical museum, the choice of method of arrangement and organization is not without its difficulties. There can be no question that in so far as these should be determined by the instructional aim, the regional and unitary method of display is ideal. Practical considerations, however, have to be taken into account; and whereas in Holland the problem has proved open to solution, in dealing with the native peoples of the British Empire provision would have to be made for a very different set of conditions. The Dutch possessions in Indonesia cover an environment limited in range; the cultures and ethnic groups relatively are neither numerous nor on the whole widely diverse in character. In the British dominions, on the other hand, the range in environment, in ethnic and cultural contrast, is world-wide. As a concrete proposal a scheme of intensive display, such as has been introduced in Holland, on a scale commensurate to the British Empire, would be wrecked at its inception by financial considerations alone. On the other hand, there is no adequate reason why certain larger units such as Africa and India, which lend themselves to a modified unitary treatment, should not receive special consideration and be the subject of intensive display.

Curators of existing collections in Great Britain will no doubt have received Mr. de La Valette's criticisms with very mixed feelings. They themselves are their sternest critics, and not all are wedded to tradition. But the museum curator, perhaps more than any other research worker, is firmly circumscribed by conditions; and the history and character of the collections, as well as the space available, limit the freedom with which problems in display may be solved.

Notwithstanding the aspersion of specimen-collecting cast upon our museums, it must be remembered that many of the exhibits are of historic interest in themselves as commemorative of early exploration, and could not be withdrawn from exhibition without loss of interest. Such, for example, are many exhibits from the Pacific in the British Museum, especially those acquired by Capt. Cook, or some of the early material from America. This brings us to the most serious point in Mr. de La Valette's indictment of museum policy in Great Britain. He alludes to a proposal to break up and distribute among other institutions in South Kensington the collections which, as the Indian Museum, form part of the Victoria and Albert Museum. These collections have as their nucleus the historic collection which belonged to the Honourable East India Company, a collection which embodies a stirring page in British history. Becoming the property of the Government after the Mutiny, it was transferred in 1870 to the Science and Art Department, later absorbed in the Board of Education when that body was formed. It thus became part of the Victoria and Albert Museum. Recently, under a new curator, Mr. K. de B. Codrington, the collections have undergone, or rather are undergoing, a process of rearrangement and selection, which departs from the æsthetic prepossession of the major collection in favour of a grouping of interests to give as full and as educative a picture as possible of India's national culture as a whole in its historical and geographical setting. Consternation aroused by this proposal to destroy what all who have examined it with any care must agree is a brilliant essay in museum arrangement on scientific and educational lines, has to some extent been allayed by an assurance received by Sir Francis Younghusband, as president of the India Society, that the collections will not be distributed, but will remain as a part of the Victoria and Albert Museum.

Satisfactory as this may seem, it is questionable whether it goes far enough. Is it to be assumed that provision will be made for the expansion which will be necessary to carry out fully the scheme now in progress of development? Unless the present divorce of antiquity from historic times is to continue, it is difficult to see how adequate provision for a satisfactory display of Indian culture can be made short of a much enlarged museum. For not only are the antiquities of the original collections, including many valuable examples of early Buddhist art, still housed at the British Museum, although the property not of the trustees of that institution, but of the Secretary of State for India, but also the span of time to be covered now goes back to the beginning of the third millennium B.C. in the civilization of the Indus valley. Further, geographically, Indian cultural study now leaps the barrier of boundaries to extend half over Asia, from Irak to Central Asia, China, Japan, Further India and Indonesia, so far as Bali and distant Celebes. The material available in the national collections—the Aurel Stein collections from Central Asia alone are unique as documentary evidence for the spread of Buddhist art and Indian influence—if brought together under one roof, would demonstrate

Indian culture in a manner possible nowhere else among the collections of the world, even in India itself.

On the grounds of public policy, the formation of a museum of Indian life and culture cannot be too strongly urged. Now that the bonds of Empire have become tenuous indeed, we hold India by a thread. But impalpable bonds, as has been shown by the visit of the British Association delegation to the jubilee meeting of the Indian Science Congress Association this month, can be made stronger than any material force. To the degree in which our future policy towards India is rooted in an understanding of Indian aspirations on the part of the British people, the greater the strength of the bond that will hold this great country within the Empire. A great Indian cultural museum would certainly contribute the major part to such an understanding. It would show that whatever the differences between the two peoples may be, to India belongs a civilization older than our own, which in art and intellectual accomplishment has been in no way our inferior, while in Buddhism it has produced a creed which more nearly than any other in the world's history approaches the way of life inculcated by Christianity.

Principles of Biological Control

The Biological Control of an Insect in Fiji
An Account of the Coconut Leaf-mining Beetle and its Parasite Complex. By T. H. C. Taylor. Pp. 239 + 23 plates. (London: Imperial Institute of Entomology, 1937.) n.p.

WORKERS in the field of applied science are often reproached by their academic colleagues engaged in pure science with their failure to publish their methods and results and with the sketchy and inadequate character of what they do publish. This complaint is based, to some extent at least, on a misunderstanding of the object of applied science, which is not, primarily, the discovery of truth, but simply the production of facts. We call in the medical man to cure our rheumatism, and the builder to put up our house. We do not expect them to write monographs on these subjects, and we should feel rather dissatisfied if we found that they were doing this instead of getting on with the job for which we paid them. A certain continuous pressure brought to bear on the economic worker often prevents him effectively from exploiting the scientific by-products of his work; and in some cases this pressure is probably both necessary and justifiable.

On the other hand, it is clear that there are vast fields of applied science in which such effective practical rules as have been worked out in medicine and bricklaying do not yet exist, where almost every conceivable practical operation is at the same time a scientific experiment, on the result of which further progress depends. In such cases, it may be impossible to draw any lesson from the work done unless the methods used and the consequence of resultant events are recorded in detail. Furthermore, though there is not necessarily any connexion between the power of doing something well and the ability to explain how it is done, it does seem that, for the full comprehension of data, explanation carried to the point of actual exposition is highly desirable. Writing up our facts for publication helps us to realize not only what we know, but also, and even more important, what we do not know.

Work on the biological control of insect pests, which is applied entomology of the most difficult and complex description, has suffered a good deal in the past, and still suffers, from the fact that scientific analysis has not kept pace with practical experiment. Great operations have been carried out in certain parts of the world of which we can scarcely say whether they have succeeded or failed, to say nothing of specifying the reasons for failure and success. Attempts have been made in recent years to deal with some of the problems of biological control by mathematical methods; but, interesting and suggestive as they are, it is only too obvious that they can never replace the observation of actual events and indeed, the investigations carried out by workers like Salt, Lloyd, Ullyett, Walker and others on the problem of host selection have made amply clear the defects of the concepts embodied in the basic equations of our mathematical theories. Fundamental work on a large scale is urgently required and although, as was pointed out in NATURE of February 20, 1937 (p. 304), the authorities concerned with operations in biological control in the British Empire have not yet provided for it, satisfactory progress cannot be made until the need is met.

In these circumstances, we feel sure that every student of biological control will heartily welcome Dr. T. H. C. Taylor's fascinating monograph on the successful control, by parasite introduction, of the coco-nut leaf-mining beetle in Fiji. Dr. Taylor was one of the entomologists associated with Dr. J. D. Tothill in the brilliantly successful work he carried out in Fiji on the coco-nut moth. These entomologists have consistently adhered to the practice, which we are here advocating, of exploiting the scientific aspect of their problems to the full, so that they and all the other workers in the field have not merely the satisfaction of a spectacular success, but also a reasonable explanation of how it has been obtained.

The subject of Dr. Taylor's work is the leaf-mining hispid beetle, *Promecotheca reichei* Baly., which is injurious to coco-nuts in Fiji, Samoa, Tonga and some of the intermediate islands. It is attacked in its native home by a number of natural enemies which, in normal circumstances, are able to keep the pest under control. In comparatively recent years, however, this natural equilibrium has been disturbed owing to the accidental introduction of the well-known parasitic mite *Pediculoides ventricosus*. This mite is able, under favourable conditions, to destroy a very large proportion of the hispids ; but it is unable to maintain permanent control. The actual outcome of its work is to produce gaps in the sequence of host material of such a character that the original native parasites suffer severely and outbreaks of a very serious character occur. The practical problem, then, was to find in some other areas parasites capable of reproducing on *Promecotheca* and able to bring it under control in the abnormal condition created by the mite *Pediculoides*. Dr. Taylor's account of the attack on this extraordinary problem, which was eventually solved by the introduction of a chalcid parasite found on other leaf-mining hispids in Java, is of great theoretical and practical interest and contains a mass of valuable and illuminating observations on the biology and interrelations of the various species involved.

A few minor criticisms may be made. The work is adorned with a large number of beautiful and costly plates, the like of which few entomologists are able to secure for their papers in these days ; but the anatomical details there represented, though perhaps sufficient for the purposes of their particular problem, are, according to our modern standards, inadequate. In some cases, Dr. Taylor's account of events, though highly interesting and plausible, rather fails to produce complete conviction, because the basic numerical data have not been exhibited in sufficient detail. At one point (p. 16), he gives a surprisingly full account of the variation in the *Promecotheca* population before the advent of the white man in the islands, which the present writer found a little staggering. The suggestion (p. 204) that the limited quantity or unusual quality of the food of parasite larvæ "causes them to become male by a process in the nature of castration" also requires amplification.

In regard to this and other matters the author shows signs of isolation from other workers due partly no doubt to the circumstances of his work and the habit engendered by it of doing everything single-handed. We think, also, that his paper could have been compressed with advantage. Nevertheless, it is, as it stands, a highly original and stimulating monograph, and a striking example of what individual effort can accomplish as against mere mass organization.

A Statistical Survey of the Stellar Universe

Lehrbuch der Stellarstatistik
Von Prof. Dr. E. v. d. Pahlen. Unter Mitwirkung von Dr. F. Gondolatsch. Pp. xvi + 934. (Leipzig: Johann Ambrosius Barth, 1937.) 96 gold marks.

THE title of this book gives a rather bald impression of its contents, and we may be permitted to amplify it into "the spatial and dynamical structure of the stellar universe, based on the observed statistics of stellar magnitudes, spectra, masses and motions". Our first word must be one of welcome for this encyclopædic volume. If we leave out of consideration the relevant portions of the "Handbuch der Astrophysik" (a work in which there is considerable, but excusably unavoidable, overlapping, due, of course, to the different predilections and points of view of the several experts concerned) the present volume is the first systematic treatment of the subject since Eddington's classic "Stellar Movements and the Structure of the Universe" was published nearly a quarter of a century ago. When we consider the immense amount of observational and theoretical investigations during the last two decades, it is indeed surprising that an attempt has not been made before this to gather into a coherent whole the researches of a multitude of workers in this important field.

Dr. v. d. Pahlen's general mode of treatment is the historical, and the principal contributions to the several sections are described in roughly chronological order. There is a lot to be said for this procedure, but, on the other hand, the magnitude of the book tends to become of almost astronomical dimensions, and this may well prove a real defect so far as its circulation in astronomical circles is concerned. Again, the author's thoroughness in dealing with his subject is commendable, but, to a large extent, it is unnecessary, especially in the earlier stages; it is scarcely likely that the reader of the book will be wholly unacquainted with the elementary principles of astronomy, such as the measurement of right ascension and the classification of spectra—to take only two examples. Our view is that the book is, in the first instance, a specialist's book and, in the second, a work of reference; accordingly, we feel that its value would have been greatly enhanced by a judicious—and, in some places, a severe—pruning of elementary and other topics that are dealt with in more general publications.

It is scarcely possible to give, within the compass of this review, more than a rough sketch of the contents. The first part—amounting to a little less than one sixth of the whole volume—is concerned with the mathematical development of statistical theory and, in particular, with the discussion of normal and skew frequency functions and the theory of correlation. This section had been written by Dr. Hufnagel, whose death, five years ago, deprived Dr. v. d. Pahlen of an experienced collaborator almost at the outset of the project the fruition of which is seen in the present volume. It may be interpolated here that three chapters in later parts of the book—amounting to about 130 pages in all—are from the pen of Dr. F. Gondolatsch of the Recheninstitut, Berlin-Dahlem. The mathematical methods developed in the section under consideration bear the impress of the influence of the Lund school and, in particular, of the late Prof. Charlier; the section is a clear and comprehensive exposition of the subject as formulated. It is to be remarked, however, that the plan of systematic comprehensiveness has partially broken down here, as the theory of combining observations according to well-known methods—such as we find in the solar motion problem, to take a simple instance—is omitted.

The second part of the volume, amounting to two hundred pages, deals with the observational side of the subject, namely, the determination of such stellar characteristics as position, proper motion, radial velocity, brightness, colour, spectrum and parallax. This is one of the sections where the reviewer's earlier criticism applies in considerable measure. However, apart from this, the author has done his work exceedingly well, and the reader will find all the information about past and modern observational practices that he is likely to require. In the latter pages of this section the usual methods of deriving statistical parallaxes are developed in full; the work of Kapteyn and van Rhijn in this interesting field is described at length and correlated with the theoretical formulæ derived about a quarter of a century ago by Schwarzschild. An omission of theoretical and of some practical importance concerns the effect of the well-known systematic motions of the stars on the mean parallaxes derived according to the methods described.

The third, and the longest, section of the work is concerned with the space distribution of the stars. Numerous investigations on this subject depend on an initial assumption as to the mathematical form of the stellar density function, with or without a further assumption as to the law governing the distribution of the absolute magnitudes of the stars investigated. This mode of procedure is dictated by the fact that our knowledge of stellar distances, as determined by direct or ancillary methods, stops short at a comparatively trifling distance from the sun. On the other hand, the apparent magnitudes of the stars can be determined easily and accurately. In general, apparent magnitude is not a completely satisfactory criterion of distance, but, with the stars segregated according to colour-index, statistical investigations based on counts of stars of different apparent magnitudes are of undoubted value in giving us reasonably trustworthy information as to the structure of the stellar system. A second line of attack is based on the observed proper motions of the stars; it may be remarked that proper motion is a much better criterion of distance than apparent magnitude. The author gives also a full account of the methods based on Schwarzschild's integral equations. Within the last ten years, a serious complication to the statistical methods has been introduced by the discovery of well-marked galactic absorption—in this connexion Trumpler's investigation of open clusters may be mentioned as placing beyond doubt the existence of a comparatively thin absorbing layer in the equatorial plane of the galaxy. The author describes fully and successfully most of the fundamental investigations carried out within recent years, with commendable emphasis on the present situation as created by the discovery of galactic absorption.

The fourth and final part of the volume deals with the kinematics and dynamics of the stellar system. It may be noted in passing that there is a certain amount of unnecessary reiteration in connexion with the solar motion. Kapteyn's two-streams theory and Schwarzschild's ellipsoidal hypothesis concerning the systematic motions of the stars are treated fully. Schwarzschild's original papers are not readily accessible and the detailed account of his methods as presented by Dr. v. d. Pahlen will be welcomed. Of the two mathematical formulations of the systematic motions of the stars, Schwarzschild's is the more convenient, from the analytical point of view, in theoretical investigations in stellar dynamics, a subject which has received an increasing amount of attention during the last decade, on both the observational and the mathematical sides. The author gives a good, though not quite complete, account of the researches in this field. The theories of galactic rotation associated with the names of Oort and Lindblad are described at length, and the observational material patiently gathered in recent years has been summarized in tabular form.

Dr. v. d. Pahlen is to be heartily congratulated on completing this authoritative volume, which will prove indispensable to present and future workers in the field surveyed.

W. M. S.

Asiatic Yams

An Account of the Genus Dioscorea in the East Part 1: The Species which Twine to the Left. By D. Prain and I. H. Burkill. (*Annals of the Royal Botanic Garden, Calcutta*, 14, Part 1.) Pp. 210 + vi 91 Plates. (Alipore: Bengal Government Press, 1936.) 75 Rs.; £5 13*s*.

THE yam, the tuber of various species of *Dioscorea*, is a staple food in the tropics and commonly cultivated, especially in India, Malaya and tropical Africa. The two volumes under notice, which maintain the excellence of production of the *Annals of the Royal Botanical Garden, Calcutta*, form the first part of an account of the Oriental species by two eminent botanists who, by thirty years of careful investigation, have specially qualified for the task.

The genus is a large one and has been the subject of monographs by previous botanists, who, however, have had at their disposal mainly herbarium material. The origin of the present monograph dates from the difficulties experienced by the late Sir Joseph Hooker when revising the genus for the "Flora of British India", and by the late Sir George Watt in his efforts to elucidate the cultivated species for his "Dictionary of the Economic Products of India". Hooker, in 1892, found the species in a state of indescribable confusion, and the food-yielding species for the most part indeterminable. He begged Watt and Sir George King, then in charge of the Calcutta Garden, to grow, not only all the food-yielding forms, but also as many of the uncultivated species as could be procured. In 1898, on King's retirement, the collaboration devolved on Sir David Prain, his successor, and in 1901 Mr. Burkill took over from Watt. When the senior author left India in 1904, Mr. Burkill continued the systematic study of the living material in cultivation in the Garden, and when transferred to Singapore in 1912 extended his study to species outside the limits of India. Since his return to England in 1925, he has continued his work at Kew. Material has also been examined in or from all the important herbaria at home and abroad.

Part 1 includes the species that climb to the left, comprising nine of the ten sections into which the authors divide the genus. Part 2 includes the species that climb to the right, that is the large section *Enantiophyllum*, and also a tabulated account of the distribution of the species, a phytogeographical review and the history of the various collections that have been studied. Text and plates are already in print and these should appear shortly.

The authors, for sake of completeness, have included the very rare Pyrenean species *D. pyrenaica*, the sole representative of the anomalous section *Borderea*, a dwarf, non-climbing plant which in some characters recalls the temperate Old World genus *Tamus*—the black bryony of our hedges; also two species respectively from the Balkans and the Caucasus that are allied to oriental species.

The ten sections under which the species are grouped represent an arrangement differing from those of previous monographers, which are critically examined by the authors. Thirty years' experience of cultivating the oriental species indicates that the subgenera recognized by E. B. Uline in the "Pflanzenfamilien" (1897) and by R. Knuth in the "Pflanzenreich" (1924) should be discarded.

The general description includes a study of the formation of the food-storage organ—tuber, rhizome or corm—by which the plant persists from season to season and which supplies prime characters for the construction of groups of sections. Opinions have differed as to the morphology of the tuber, which has been regarded as a root structure, or by Goebel as an organ *sui generis* combining the characters of root and shoot. The authors, however, are convinced that it is a stem structure.

The form of the leaf shows great variety on a simple cordate type, but in two sections palmately compound leaves occur. The male flowers, capsule and seed also afford distinctive characters.

Seventy-six species are recognized, and the thoroughness of the work is indicated by the very large proportion that have been described by the authors in the course of their studies. Synonymy is given in full and expresses the confusion to which Hooker referred, dating back sometimes to Linnæus himself. The species are very unequally distributed among the sections; elaborate keys are supplied for their identification. Each species is described at length and each description is admirably supplemented by a plate which, whenever possible, includes details of form of the storage organ, together with figures of leaf, flower and fruit. Dialect names are discussed, and economic uses, mainly as food, for which often careful preparation is required that poisons may be removed which have also economic uses. Geographical distribution is given in very great detail, and every specimen examined is cited.

The production of the plates, which suggests a crayon drawing, is pleasing. Some are by native artists, others by the late Matilda Smith of Kew and others by Mr. Burkill himself. There are also five plates of maps indicating the geographical regions recognized and the distribution of the individual species. The financial aid of the Bentham-Moxon fund towards the production of the plates is acknowledged.

Theory of Fourier Integrals

Introduction to the Theory of Fourier Integrals
By Prof. E. C. Titchmarsh Pp. x + 390. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 17*s*. 6*d*. net.

SINCE the publication of Prof. Zygmund's "Trigonometric Series" in 1935, there has been considerable demand for another book dealing with trigonometric integrals. Prof. Titchmarsh's book meets this demand. He is already well known to students of mathematics by his text-book on the theory of functions, and his new book comes up to the high standard of the former.

After two more or less introductory chapters, Prof. Titchmarsh devotes a chapter to the theory of Fourier transforms in the class L^2, that is, the class of all functions whose squares are integrable in the Lebesgue sense. This is undoubtedly the most important part of the subject. The theory centres round a very beautiful theorem due to Plancherel, which asserts that every function (x) of Lf^2 has a Fourier transform $g(x)$ also in the class L^2 and

$$\int_{-\infty}^{\infty} \{g(x)\}^2\,dx = \int_{-\infty}^{\infty} \{f(x)\}^2\,dx.$$

Plancherel's original proof was published in 1910, and since then other proofs have been given by various writers. Prof. Titchmarsh gives four of these proofs, including Nobert Wiener's very interesting proof, of which the chief feature is the use made of the Hermite polynomials.

The Lebesgue theory of integration is fundamental in all this work, and in reading this chapter no one can fail to be impressed by the tremendous amount which the theory of Fourier integrals and mathematics generally owes to Lebesgue's definition of the integral.

The chapter on Fourier transforms in L^1 is followed by another on transforms in L^p. The symmetry which exists in L^2 is of course lost in other Lebesgue classes. There are, however, analogues for most theorems. Among the other topics treated may be mentioned the general theory of transforms and the theory of conjugate functions. The last two chapters are devoted to applications to the solution of differential equations and integral equations respectively. In the latter chapter, examples are given of the use of Fourier transform methods in the theory of probability and statistical dynamics. The book concludes with a long bibliography.

Prof. Titchmarsh is to be very warmly congratulated on his book. As the title implies, it is primarily an introduction to the subject and does not cover the whole field. The author has not attempted to give an account of all the recent developments, especially the more specialized ones. Those who wish to pursue the subject further can refer to Wiener's "Fourier Integral", Boehner's "Vorlesungen über Fouriersche integrale" and, above all, Paley and Wiener's, "The Fourier Integral in the Complex Domain". Fourier integrals have much in common with Fourier series, and this subject has been very adequately treated in Zygmund's book, to which reference has already been made.

The book under notice is probably of more interest to analysts than to applied mathematicians, but the latter might find much that interests them. No one should be put off by the Lebesgue theory of integration, as it is only necessary to know a few of the properties of the integral, especially those concerning strong convergence. The book contains a sufficient number of examples, including applications to mathematical physics, to illustrate the scope of the methods. A. C. OFFORD.

Raum oder Zahl?

Von Cl. H. Tietjen. (Schule im Aufbau aus volkischer Wirklichkeit, herausgegeben von Cl. H. Tietjen, Band 6.) Pp. 51 + 4 plates. (Leipzig: Friedrich Brandstetter, 1936.) 1.59 gold marks.

SPACE or number? Is the infant intelligence to be inclined towards mathematics by curiosity about shapes and patterns, or do we perceive that there are as many oranges as apples before we recognize a common quality of roundness? Artificial questions, we may think, but at least we take for granted that they are questions for the psychologist. It seems that we are wrong. According to a work which claims the support of the German Ministry of Education, they are questions of immense importance, and questions for the ethnologist and the politician. Fortunately the answers in Germany at least are perfectly definite, for the alternative, space or number, is the same as the alternative, German or Jew.

The Nordic race has a native feeling for space, which it is the duty of every teacher to foster, and German children, from their earliest years, must be protected from the logic which curses the mathematics of the Latin and Semitic peoples. Even the application of numbers to geometry is a danger, for we cannot report the direction of approach of hostile aircraft in terms of Cartesian co-ordinates, and the only hope of safety for a nation to-day is that every member of it should be a competent military observer. It is true that even altazimuth observations are a kind of measurement; fortunately their use is not a development from analytical geometry or a debt to Asia, for it is implicit in the most rudimentary astronomy, and it is intuitively certain that the regular movements of the heavenly bodies were studied and understood by the German inhabitants of the north of Europe long before the rise of Chaldæan civilization. So now we know. E. H. N.

Faune de France

31: Homoptères auchénorhynques, 1 (Typhlocybidæ). Par Prof. H. Ribaut. (Fédération française des Sociétés de Sciences naturelles: Office centrale de Faunistique.) Pp. 230. (Paris: Paul Lechevalier et fils, 1936.) 60 francs.

THE advent of the present part of the "Faune de France" series will be welcomed by all students of Hemiptera. It deals with leaf-hoppers of the group Typhlocybidæ, which are often difficult to identify, and much confusion has existed with regard to certain of its members. Although more usually classified as a group of the Jassidæ, M. Ribaut separates the Typhlocybidæ from the latter on venational characters. Revision of the British species has long been needed and the appearance of this volume will prove a valuable aid to their identification since almost all of them are represented in the French fauna. Twelve new species and several new varieties are described, some also being recorded from England, and are consequently not yet recorded in any English work.

It may be mentioned that certain species (from England, Germany, etc.), which are not at present known from France, are also included in view of the probability of their subsequent discovery. Extensive use is made of the genitalia, which afford essential specific characters. The need for accurate illustrations of these parts is fully appreciated and well catered for; no amount of descriptive text alone can convey the same clear impressions of the structural complexity involved. It is hoped that M. Ribaut will see his way to provide the companion volume on the Jessidæ at a not very distant date.

The Torch-Bearers

By Alfred Noyes. Pp. vii + 422. (London: Sheed and Ward, 1937.) 7*s*. 6*d*. net.

THE man of science, though he must be full of imagination and insight as the veriest poet, has rarely become known as a writer of verse; and strangely enough, when he has shown a flair for poetry, it has not generally been inspired by the subject of his own studies. The poet, so far as he has touched upon natural science, has been content to let his muse play upon the phenomena of Nature, the sun, the stars, the clouds, the trees, the woodlands and their inhabitants. To Mr. Alfred Noyes belongs the credit of seeing in the wonders of scientific achievement a theme which can stir the soul with deep emotion, and in the workers who have dedicated themselves to the pursuit of science a band of torch-bearers, handing on the flame of knowledge through the ages. His trilogy appeared originally in three parts, which were reviewed appreciatively in these columns as they appeared (NATURE, May 20, 1922, July 18, 1925, and March 7, 1931). The issue of the three parts in a single volume, at a very modest price, will be much appreciated.

Aristotle's Physics

A revised Text, with Introduction and Commentary, by W. D. Ross. Pp. xii + 750. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) 36*s*. net.

THIS scholarly work has been received by students and specialists alike as an invaluable addition to Aristotelian literature. The Introduction and Commentary are masterpieces of their kind and help considerably the understanding of a natural philosophy which does not correspond with modern views, but which inspired scientific thought until the advent of Galilean mechanics. The physics of Aristotle, however, have more than a historical value: they help to form a more accurate view of the whole Aristotelian synthesis, and of the scientific problems which were discussed in classical antiquity. Further, its philosophical foundations could still be used to-day; have we not heard scientific workers heralding a return to Aristotelianism in natural philosophy? The printers have taken considerable care in producing a Greek text as faultless as possible, and have thus secured a share in the praise which the book rightly deserves. T. G.

The Scientific Activities of Sir Charles Parsons

THE second Parsons Memorial Lecture was delivered on November 25 last by Dr. Gerald Stoney at the Institution of Electrical Engineers. As Sir Frank Smith in the first of these lectures, given at Newcastle-upon-Tyne a year earlier, had dealt at length with the invention and application of the steam turbine, Dr. Stoney devoted his lecture to the less well-known activities of the great engineer. This was a subject for which he was pre-eminently fitted, for he was closely associated with Sir Charles Parsons during his most prolific period. Parsons himself once spoke of Dr. Stoney as having grown up with the Heaton Works of Messrs. C. A. Parsons and Co., but he was also closely connected with the work of the Parsons Marine Steam Turbine Co. Much of what he had to say was therefore of great historical interest.

The question may well be asked what led Parsons to the conception of the steam turbine. At the outset, Dr. Stoney answered this by recalling that, when quite a young man, Parsons was interested in the production of power from the kinetic energy of a jet of gas. His first efforts in this direction were applied to the development of torpedoes, which were driven by the kinetic energy of gases produced by the combustion of an explosive. His ideas were also largely influenced by noticing the analogy between the flow of steam under small differences of pressure and the flow of an incompressible fluid like water. At Heaton is preserved a model boat (Fig. 1) the propeller of which was driven by the action of compressed air. The screw propeller is fitted beneath the centre of the boat and is surrounded by a double shrouding carrying blades on which the jet of air impinged. It is evident, said Dr. Stoney, that this work led to the conception of the steam turbine.

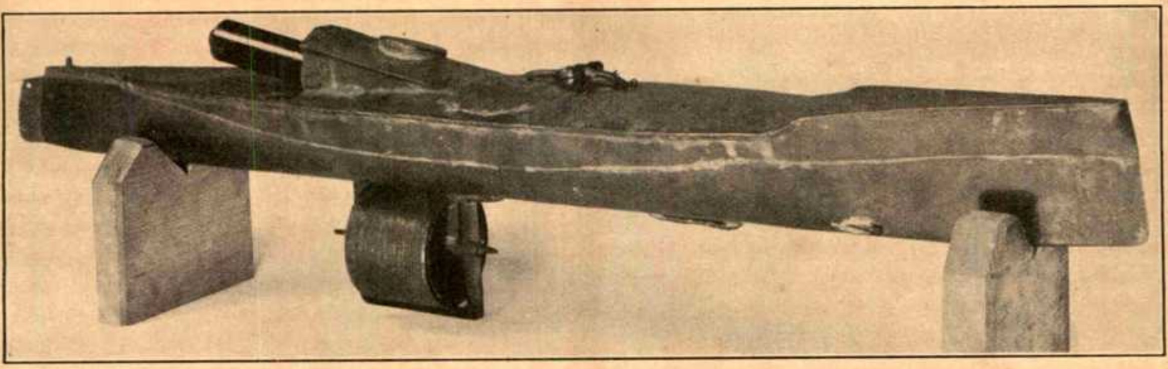

Fig. 1.

MODEL BOAT, DESIGNED BY SIR CHARLES PARSONS, DRIVEN BY COMPRESSED AIR.

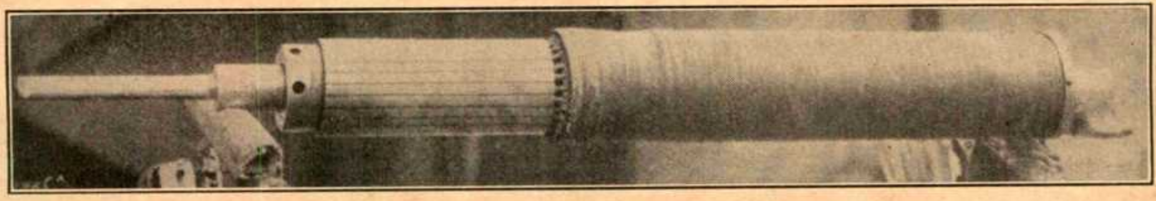

Fig. 2.

ARMATURE OF THE FIRST PARSONS TURBO-GENERATOR.

Though he was influenced by analogies between the flow of steam and the flow of water, Parsons never told anyone, not even the most trusted members of his staff, how he arrived at the design of an actual machine for any given conditions. Possessing high mathematical ability, he was rarely, if ever, known to make use of formal mathematical reasoning for the solution of any problem. He had a thoroughly scientific mind and scientific habits of thought, and his results were the outcome of these, rather than of any deliberate calculations. In the early days, he would come into the office with a scrap of paper on which were written particulars of the blading he had decided upon for a certain turbine. These were set out to scale and modified if necessary according

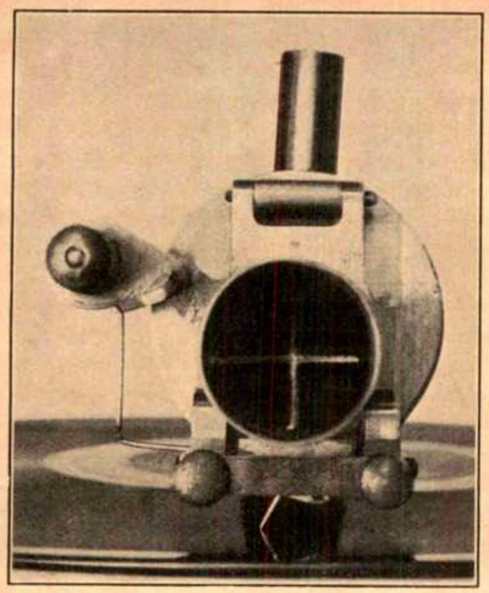

Fig. 3.
THE AUXETOPHONE MOUNTED ON A GRAMOPHONE RECORD.

to his judgment. The staff was completely puzzled as to how he determined the proportions of the blading. It was doubtful if he ever possessed a slide rule, and indeed seemed to have no need for such a thing. He could work out results in his head or on paper as quickly as most people could obtain them on a slide rule, though he never explained the process and it is doubtful if he could have done so.

It never seemed to Parsons that his powers were exceptional. He had an extraordinary intuition on all matters connected with design. No matter how difficult or novel the problem, he seemed to know instinctively how to solve it. He also had great mechanical aptitude. He was perfectly familiar with all workshop processes, and had unusual skill with his hands. He took a delight in making models, not as ends in themselves, but as a means of studying some problem.

It was in 1884 that Parsons made his first turbo-generator. This developed about 4½ kw. at 18,000 revolutions per minute. The dynamo had to be specially designed, for dynamos at that time revolved at about 1,200 revolutions per minute. The armature of this first turbo-generator (see Fig. 2) was only about 2⅝ in. in diameter. Every pound weight at the surface of it had a centrifugal force of about 5 tons at the normal speed of the machine, so great care had to be taken to make the construction sufficiently strong to resist mechanical stresses. Few better examples of Parsons's intuition, said Dr. Stoney, can be given than the fact that the proportions of his first turbo-dynamo, designed fifty-three years ago, when electrical knowledge was so rudimentary, could scarcely be improved upon to-day. After further references to the development of turbo-dynamos and turbo-alternators, Dr. Stoney remarked: "Some of the practices of these early days must now appear very primitive, but one must remember that Parsons was breaking new ground in almost every direction. Books such as we have in abundance to-day on steam, electricity and every branch of engineering were either non-existent or extremely elementary. Measuring instruments, as we know them to-day, did not exist and the range of materials for constructional and insulating purposes was very restricted."

The record of the work of Parsons on the turbo-generator formed the first half of Dr. Stoney's lecture, and he then turned to consider the work of Parsons on condensing plant, turbo pumps, fans and compressors, cavitation, the erosion of marine propellers and matters less closely associated with engineering. It will perhaps come as a surprise to many to learn that when Parsons was deeply immersed in his early study of the turbine and the dynamo, he should have turned to the manufacture of electric lamps. In 1885, when a partner in the firm Clarke, Chapman, Parsons and Co., he founded the Sunbeam Lamp Company, making arc lamps and incandescent lamps. At

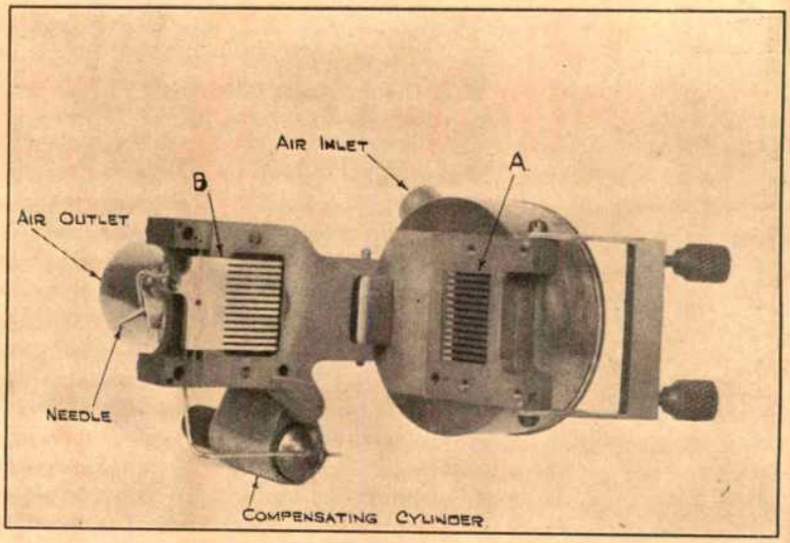

Fig. 4.
THE AUXETOPHONE OPENED TO SHOW PARTS.

first small lamps were made, but after a legal decision in a patent action that a 'filament' was less than $\frac{1}{32}$ in. in diameter, the Company restricted itself to the production of lamps having 'carbons', not 'filaments', of $\frac{1}{32}$ to $\frac{1}{8}$ in. diameter. The lamps ranged from 100 to 3000 c.p. At the Newcastle Exhibition of 1887, lamps made by the Sunbeam Co. were used for lighting, the current being supplied by ten Parsons turbo-dynamos ranging from 16 kw. to 32 kw. in capacity. Little information has been preserved as to the processes used in the manufacture of the lamps, but the material for the carbons appears to have consisted of tar, a special anthracite and zirconium.

To the same early period—the 'eighties—belongs the early optical work of Parsons, which began with the manufacture of parabolic mirrors for searchlights. He devised a process for bending the glass while hot in an accurately figured cast-iron mould, and his methods are used to-day with very little alteration. Several hundred mirrors per month are now turned out at Heaton for searchlights and other purposes. He had always a liking for optical work, no doubt inherited from his father, the Earl of Rosse, whose 6 ft. telescope at Birr was the wonder of the astronomical world. After the Great War, Parsons purchased the optical glass works set up by the Government near Derby and acquired a controlling interest in the firm of Messrs. Ross, Ltd. A year or two later he acquired the works of Sir Howard Grubb at St. Albans, and forming the firm of Sir Howard Grubb, Parsons and Co., Ltd., founded new works at Walker Gate, close to the Heaton Works, and it was there the 74-in. telescope for Toronto, the largest in the British Empire, was built.

Parsons's interest in other scientific matters was shown by his suggestion for a very deep bore hole, his experiments on the artificial production of diamonds, his experiments on the compressibility of liquids and his invention of the auxetophone. About 1902, when phonographs and gramophones were becoming popular, he realized that their reproduction of sound was far from satisfactory. He therefore decided to make a reproducer worked by compressed air by which the sound waves should be generated more in accordance with the action of an organ pipe than that of a telephone receiver. Then followed experiments on the flow of air and trials with various types of valves which could be controlled by the needle of the gramophone. Figs. 3 and 4 show the auxetophone mounted above a gramophone record, and open to show the valve and its seating. The moving part of the valve, about $\frac{1}{2}$ in. by $\frac{3}{4}$ in., was a flat comb of magnalium. Air at about 2 lb. per square inch was supplied to the wind-box through a flexible tube. Such a valve, said Dr. Stoney, made thirty-five years ago, reproduced sound with a volume and quality which have only recently been equalled by wireless loudspeakers and electric gramophones. The auxetophone was also applied to musical instruments, and was used with success in the orchestra at the Queen's Hall, London, in 1906. The invention of this instrument was entirely the work of Parsons's leisure hours, just at the time he was engaged in the application of steam turbines to naval vessels and fast mercantile ships.

Heat Production, Nutrition, and Growth in Man: Some New Views*

By Dr. E. P. Poulton

CONSTANCY OF CARBON DIOXIDE

Series of basal metabolism observations on the same individual have been published by a number of observers, and analysis shows that when the previous diet did not contain much carbohydrate the carbon dioxide tended to remain more constant than did the oxygen, which fell as the quotient rose. When the previous diet was rich in carbohydrate there was a tendency for the carbon dioxide to rise. It will be shown that a constant carbon dioxide as shown in Figs. 1 *a* and 1 *b* is in favour of the theory of the constant combustion ratio, and, such being the case, further observations would be desirable to prove definitely the relation of this constancy to the diet taken. According to this theory, the carbohydrate and fat are always burnt in a fixed ratio corresponding to a quotient of about 0·8, and if the quotient is higher there is a simultaneous conversion of carbohydrate to fat and if lower a conversion in the opposite direction. Such a theory cannot be proved by metabolic determinations on the whole organism between the respiratory quotients for the combustion of pure fat and pure carbohydrate, because it would make no difference whether with a higher quotient a higher proportion of carbohydrate was burnt or whether the same amount was burnt as before and the extra amount disappeared by being

*Continued from p. 147.

turned into fat. But biochemically in the organism there might be a big difference between the two theories, because combustion of carbohydrate and fat in a fixed ratio might be occurring in one place, while a simultaneous conversion might be occurring elsewhere in the organism. Cathcart and Markowitz have also pointed out that it would be absurd to suppose that conversion suddenly began just as the quotient rose above 1, and that it probably does begin at a much lower quotient.

A detailed study of all DuBois's results, which it is hoped will be published in the *Guy's Hospital Reports*, shows that all the variations in respiratory quotient and measured heat are compatible with the theory of the constant combustion ratio and that those between the respiratory quotients for the combustion of fat and carbohydrate are compatible with both theories. There are any number of ways in which the carbon dioxide, oxygen and heat can change so as to comply with the variable combustion ratio; but there is only one simple way that satisfies the theory of the constant combustion ratio, and that is when the carbon dioxide remains constant as the quotient varies.

For example, in Table 1 are given the amounts of carbon dioxide, oxygen and heat produced by the combustion of (1) carbohydrate, (2) fat at varying quotients on theory 1, according as (*A*) the carbon dioxide remains constant, (*B*) the oxygen remains constant, (*C*) the heat remains constant. The values are calculated from a Zuntz-Schumburg table deduced from the figures given (p. 70) in the *Guy's Hospital Reports* (85, 56; 1935); but the argument is unaffected by the particular Zuntz-Schumburg relation used. Any number of other tables could be calculated with variation of both oxygen and carbon dioxide with the quotient. The point is that all the tables resemble one another in the increased amount of carbohydrate and diminished amount of fat burnt with rise of quotient, and if the experimental results agreed with any of the tables the theory of the variable combustion ratio would be applicable; there is no reason on theoretical grounds for choosing *A*, *B*, *C*, or any other combination.

When, however, in Table 2 the results are expressed on the theory of the constant combustion ratio, in *A* where the carbon dioxide is constant (it is assumed that at a respiratory quotient of 0·8 combustion in a fixed ratio is alone taking place), the simplest state of affairs is obtained; this is because on this theory carbon dioxide can only result from combustion (*loc. cit.*, p. 68) and oxygen plays a part both in combustion and in conversion. In *B* and *C* and in all other calculations we have to assume that at other respiratory quotients than 0·8 not only is conversion occurring, but there is a variation in the amount of combustion too. In all cases about 4 calories are given out or absorbed in the conversion process per litre of oxygen involved, which is equivalent to 2·1 calories per gram fat as previously calculated (*loc. cit.*). Of course, it is not necessary to take 0·8

* The Cals. per l. oxygen used in conversion are obtained by dividing these figures by those two lines above.

as the respiratory quotient for pure combustion; this method of calculation would be valid for any other respiratory quotient.

It was pointed out above that Benedict's results could not be explained on the theory of the variable combustion ratio. But on applying the theory of the constant combustion to them there is this difficulty, namely, that more heat is liberated at high quotients than would be accounted for by the combustion of the constant carbohydrate-fat mixture and a simultaneous conversion of carbohydrate to a less oxygenated compound; this would mean that removing oxygen from the molecule of an organic compound caused an evolution of heat, that is, diminished its heat of combustion, a condition unknown in thermochemistry. It is only right to point out that Benedict and Carpenter themselves do not now place reliance on these early results of theirs, because the oxygen determinations were not very accurate. Dr. Carpenter has kindly sent me the figures for the eliminated heat in Figs. 1 *a* and 1 *b*, and it does not seem possible to account for the discrepancy by a wide difference between the direct calorimetry and the eliminated heat. I must accept their explanation, though I have already pointed out that the oxygen values in the alcohol control experiments were satisfactory, and it will be necessary to assume a large error in the oxygen.

Summarizing—on the theory of the variable combustion ratio, a carbon dioxide that rises, falls or is stationary with rise of quotient is equally probable; and this theory is not applicable to the higher quotients; on the theory of the constant combustion ratio a constant CO_2 would be expected and this is, in fact, usually found. Further, this theory is applicable to all quotients. Hence, if the facts are looked at *de novo*, paying no attention to the views held from the beginning of the century up to the present day, this theory would probably be chosen.

It must be admitted that this theory is not altogether unreasonable. Many quantities associated with the human body have in health a more or less constant value. The body temperature at rest varies within comparatively small limits, and the same is the case with the hydrogen ion concentration of the blood and the quantity of phosphocreatine broken down in relation to muscular work; while the amount of sleep remains the same for an individual at any particular age. Why should not carbohydrate and fat be burnt in constant proportion in the post-absorptive condition in a normal healthy man. The story of Cain and Abel suggests that the diet of primitive man was variable in its carbohydrate and fat content, depending on his success in cultivation, when it would be mainly carbohydrate, or hunting, when it would be mainly protein and fat. Which is most likely, that the complicated metabolic processes resulting in the actions of the heart, muscles and glands should be entirely at the mercy of the individual's caprice (or luck) in his choice of food, or that these processes should in the main run always along well-defined lines of chemical and physical action, while any foodstuff taken in unusual quantities is stored in some suitable form for future use, even though this means a conversion of some kind ? Is it not reasonable to look on these conversions of food as some of the earliest adaptations that the organism has acquired in the course of evolution, and, as Dr. H. E. Magee has suggested, this would be a reason for the evolution in the body of the power to manufacture the ferment glutathione, which is otherwise without a clear explanation.

A NEW DEFINITION OF BASAL METABOLISM

On the theory of indirect calorimetry, based on the constant combustion ratio of carbohydrate and fat, the non-protein carbon dioxide results entirely from the combustion of carbohydrate and fat, while the oxygen is used partly for combustion and partly in conversion processes. If the respiratory quotient is high, say, 0·9, the heat, calculated on the assumption that the oxygen is used entirely for combustion, is about 8 per cent above the heat actually found, because the heat due to combustion is diminished by the heat absorbed in the conversion of carbohydrate towards fat. Since under basal conditions there are continual small variations in the quotient, there will be continual additions to or subtractions from the heat of combustion, according as the conversion of fat to carbohydrate is taking place or vice versa. Since these conversions are ephemeral and will cancel each other over a long period, they can scarcely be regarded as part of a 'standard' metabolism, and so it is much better to neglect them, and this is done by taking the carbon dioxide alone into consideration. In these circumstances the basal or standard metabolism must be defined afresh as the heat of combustion at rest in the post-absorptive state and not as the total heat measured in a calorimeter, the value of which may be a little different, depending on the respiratory quotient. If this definition be accepted it follows that the carbon dioxide alone must be measured and no account must be taken of the intake of oxygen.

Suppose, on the other hand, we retain the older but less likely theory of the variable combustion ratio, the significance of the constant carbon dioxide still remains and we should look on the variable oxygen as indicating an ephemeral increase or diminution in the proportion of carbohydrate to fat burnt, which is also not part of a standard metabolism. In either case, carbon dioxide should alone be used for the determinations, and the subject should probably take a low carbohydrate diet for 18 if not 24 hours before the experiment is carried out.

Practically, in determinations of the basal metabolism I find that the carbon dioxide does remain very constant over half an hour; the error from "aus-pumping" of carbon dioxide has been exaggerated.

Obituary Notices

Prof. G. A. Buckmaster

ON December 22, Prof. George Alfred Buckmaster died at the age of seventy-eight years. Buckmaster was one of the last of the great teachers of physiology of the late Victorian and Edwardian times, who in their teaching regarded physiology as the handmaiden of medicine. He was educated at Magdalen College, Oxford, where he held a demyship; he took a first class in the Natural Science Schools in 1881, and in the following year was elected to the Burdett-Coutts University scholarship in geology. He received his medical education at St. George's Hospital, qualifying in 1883, took his Oxford M.B. in 1885, and his M.D. in 1887. He also held the Radcliffe travelling fellowship and continued his studies in various German universities.

Buckmaster's first teaching appointment was that of lecturer in physiology at St. George's Hospital Medical School, which he held until 1905; he then became assistant professor of physiology at University College, London, and in addition, in 1909, accepted the professorship at the Royal Veterinary College. In 1919 he succeeded Prof. Stanley Kent as H.O. Wills professor in the University of Bristol, and he held this chair until his retirement in 1930. In 1934 he was elected F.R.C.S. (Eng.), *honoris causa*, a distinction of which he was very proud.

Buckmaster's first paper, "Uber eine neue Beziehung zwischen Zuckung und Tetanus" was published in the *Arch. f. Anat. u. Physiol.*, and was followed by a note in the *Proceedings of the Physiological Society* on a new relation between "Contraction and Tetanus". Buckmaster was selected as one of the three English members of the Leprosy Commission in India, 1890 and 1891; the results of this work are embodied in papers in the *Leprosy Investigation Journal* and in the report of the Commission; a good deal of useful information was collected, but nothing very definite was found with regard to the causation and treatment of the disease; they produced a culture, but I gather that this has not been accepted.

During his time at St. George's Medical School, Buckmaster had abundant opportunities of investigating not only normal but also pathological bloods. The results of such experiences were embodied in a series of lectures, given in the Physiological Laboratory (South Kensington) of the University of London and afterwards published in 1906 in book form under the title "The Morphology of Normal and Pathological Blood". In one chapter he gives an account of observations carried out by himself and two colleagues, Dr. Chas. Slater and Mr. C. T. Dent, during two successive years in the Alps (Mont Blanc) on polycythæmia at high levels. In another he gives a masterly discussion of the question of the existence of blood platelets in unchanged blood, and to the end of his career Buckmaster held strongly to the view that blood platelets were artefacts.

In the year 1906, Buckmaster and J. A. Gardner collaborated in the study of the mechanism of chloroform anæsthesia, and their experimental results and conclusions are detailed in a series of papers in the *Proceedings of the Royal Society* between 1906 and 1911, dealing with methods of estimation of chloroform, with the function of the red cells in carrying the chloroform around the circulation, the rate of absorption of chloroform by the blood and its rate of elimination. In general, it was found that in the initial stages of anæsthesia the chloroform content of the blood rises rapidly to a value approaching a maximum; during this period, which occupies the first few minutes, the first danger period is reached, because the quantity of chloroform in the blood directly or indirectly affects the respiratory nerve centres, and in consequence the respirations become slower and shallower; the concentration of chloroform in the blood then falls, and the respiratory centre recovers. When the animal has passed this stage the amount of chloroform quickly rises towards a maximum value, and an equilibrium between the various factors which determine the amount of chloroform in the blood appears to be obtained. This state persists for a considerable period, and throughout the period the differences between the amount of chloroform present in the blood and that found at the lethal point is very small. The whole of the period is dangerous and the animal may die at any point should any disturbing factor come into play. They also showed that the view of some French workers that the action of chloroform is due to its decomposition in the blood with formation of carbon monoxide is erroneous; and clearly demonstrated that the carbon monoxide, estimated by the French observers by the iodine liberated on passing the gases of the blood over heated iodine pentoxide, was due to the decomposition of the chloroform vapour, contained in the blood gases, by the alkali over which the gases were passed in order to remove carbon dioxide. In a paper on the ventilation of the lung during chloroform anæsthesia they described a new form of plethysmograph suitable for use with cats.

In 1910, Buckmaster and Gardner were led to devise a new form of blood gas pump without taps or joints and ending in barometers, thus being entirely leak-proof. It was described in the *Journal of Physiology*, 1910, and in the same journal were published papers on the nitrogen content of blood, the gases in arterial and venous blood of cats, the composition of the blood gases in chloroform anæsthesia, and the composition of the blood gases during the respiration of oxygen.

While at Bristol, Buckmaster and Dr. Hickman made use of the same pump in an exhaustive investigation of the body fluids other than blood, particularly bile and urine.

Socially, Buckmaster was a delightful man. His superb memory, his wide knowledge of literature and his fund of stories of men and things made him an interesting and fascinating talker, while his deep sense of humour, his wit and his kindly loyalty of disposition endeared him to all who had the privilege of his friendship. J. A. G.

Prof. Alfred Lodge

ALFRED LODGE, who died at Oxford on December 1 of last year, so far outlived his contemporaries that it is scarcely possible now to see him through their eyes. Born in 1854, educated at Horncastle Grammar School and Magdalen College, Oxford, he was elected to a Fereday fellowship at St. John's College, Oxford, in 1876, and appointed in 1884 to the staff of the Royal Indian Engineering College, Coopers Hill, where he presently succeeded Wolstenholme as professor of pure mathematics; on the dissolution of the College in 1904 he became a master at Charterhouse, and there he remained until after the Great War.

Lodge's work in mathematics was all of the most elementary kind, but he was an enlightening teacher and a tireless computer. As a teacher he was active in the Association for the Improvement of Geometrical Teaching, and when that society broadened its basis to become the Mathematical Association, he was appropriately the first president to bear the new title; to the end of his life he was a familiar figure at the meetings of the Association.

As a computer, Lodge was a member for fifty years of the British Association Committee on mathematical tables, and it is in the publications of that Committee that his name will survive; if he did little to improve the technique of computing, he laboured incessantly in the practice, and work of his is incorporated in many of the reports, in the volume of miscellaneous tables published in 1931, in a factor table published in 1935, and in a volume of tables of Bessel functions which has just appeared; in addition to computing, he took a willing share in the discussions of the Committee and in the toil of proof-reading.

Sir Oliver Lodge writes of his brother, "He was . . . always willing to slave away in the background. . . . I have many dim recollections of his willing self-sacrifice for the family in early days". He was a secretary of Section A (Mathematical and Physical Sciences) of the British Association from 1888 until 1892, and from 1893 until 1896 he was recorder of the Section, a position so unusual for a mathematician that his appointment must be taken as a tribute to the confidence which he inspired; he served on the Council of the British Association from 1913 until 1915. The volume of tables of Bessel functions which has been mentioned is "Inscribed to their friend Alfred Lodge by his colleagues on the Committee" as a token of the warmest affection. These glimpses, which belong to different periods and come from different directions, converge: Alfred Lodge was a worthy member of the eminent family to which he belonged; his long life was a useful one, and he was a lovable man who was happy in being well loved. E. H. N.

Prof. Otto Warburg

PROF. O. WARBURG, who was well known as a botanist, was born in Hamburg in 1859. He travelled extensively for scientific investigation before being appointed lecturer in botany at the University of Berlin in 1891, later becoming professor in the Oriental seminary in Berlin.

Besides taking a very active interest in Zionism and affairs relating to colonization in Palestine, Warburg was the author of numerous botanical papers, particularly relating to tropical agriculture and economic botany. He was joint founder of the *Tropenpflanzer*, and was editor from its inception in 1897 until 1922, when he was succeeded by Dr. Busse. He was much interested in rubber plants and made an intensive study of the genus *Ficus*, particularly the African species, of which he described a great number, and he published, conjointly with Dr. De Wildeman, an enumeration of the *Ficus* of the Belgian Congo. His book "Die Muskatnus" (nutmegs) is a comprehensive account published in 1897, and still a standard work on the subject, and in the same year he issued a monograph of the family Myristicaceæ. For Engler's "Pflanzenreich" he was responsible for the screw pines (Pandanaceæ).

In his later life, Warburg devoted most of his time to the world Zionist movement, of which he became president in 1911. After the Great War, he was appointed head of the Agricultural Experimental Station in Palestine, being one of the founders, and he was also the director of the Institute of Natural History at the Hebrew University, Jerusalem. He was a man of great charm and of a retiring and scholarly disposition, and was revered by all sections of the Zionist movement.

WE regret to announce the following deaths:

Prof. W. H. Pickering, emeritus professor of astronomy in the Harvard College Observatory, aged seventy-nine years.

Dr. Carlotta J. Maury, palæontologist in the Brazilian Survey, formerly professor of zoology and geology in the Huguenot University College, South Africa, on January 3, aged sixty-four years.

News and Views

Aurora of January 25-26

A BRILLIANT auroral display was visible over most of England and from many places on the continent of Europe on the night of January 25–26. Dr. B. A. Keen, president of the Royal Meteorological Society, has sent the following account of the spectacle : "At Harpenden, Herts, the display was seen from 6.45 p.m. until well after midnight. The early stages appeared as a red glow in the north-west and later in the north-east, with a low broad green arc in between. The area of the luminous sky increased, and by 8.30 p.m. the green colour with areas of red extended well south of Orion. Up to 11 p.m. there seemed to be three periods of brilliant display : the first, and perhaps the best, at 7.45 p.m. when a bright red glow in the north-north-east was traversed by many sharply defined green and white shafts ; at 8.30 p.m. especially in the east ; and again at 9.45 p.m. when diffuse and rapidly fluctuating green streamers appeared between north-east and north-west, directed towards the zenith. Thereafter, the luminosity decreased, but as late as 11 p.m. a broad green arc stretching from north-west to north-east was still clearly visible. About midnight, a fourth display began with red streamers in the north-west, which extended until a broad red band was formed passing through the zenith to the north-east. At 1 a.m. faint red and green glows were still visible.

The Recent Sunspot and Magnetic Storms

THE large sunspot reported on p. 156 of last week's issue was easily seen with the naked eye at about the time of central meridian passage on January 18. The maximum area of the spot was more than 3,000 millionths of the sun's hemisphere ; the spot is, therefore, one of the largest half-dozen spots recorded at Greenwich since 1875. As already reported, a magnetic storm was recorded at Abinger, beginning on January 16, 22½ hr. A second and larger disturbance developed rapidly on January 22 after 5 hr. ; between 9 hr. and 10 hr. a range of 56′ in declination occurred, while that in horizontal force was 600γ. This range in H.F. had not been exceeded at Greenwich since the magnetic storm of May 17, 1921, but the maximum of the present period of disturbance had not been reached. On January 25 (a day after the big sunspot had disappeared over the western edge of the sun) a sudden commencement began at about noon and developed to a remarkable degree. The great aurora which followed is described above. A telephoned account of a preliminary examination of the Abinger magnetic traces stated that large movements of the recording magnets began at 17 hr. and were particularly marked between 20 hr. and 21½ hr. ; the disturbance died down about 3 hr. on January 26. The total ranges during the disturbance were approximately 2·1° in declination, 1,000 γ in H and 550 γ in V. The storm is probably unequalled in the Greenwich records since that of September 25, 1909. As already stated, the big sunspot had passed off the disk on January 24 and there is no other unusual spot at present visible.

Dr. G. M. B. Dobson, F.R.S.

AT the annual general meeting of the Royal Meteorological Society held on January 19, the Symons Memorial Gold Medal awarded for distinguished work in connexion with meteorological science was presented to Dr. G. M. B. Dobson, reader in meteorology in the University of Oxford. Dr. Dobson's earlier researches related to atmospheric electricity and to the structure of the atmosphere as revealed by pilot balloon observations. In 1922, in a paper on the theory of meteors contributed to the Royal Society, Dr. Dobson, in collaboration with Prof. A. Lindemann, adduced the first reasoned evidence of the existence of high temperatures in the atmosphere above 50 km. Since 1923 he has extended most fruitfully the method of Fabry and Buisson for the study of the absorption of ultraviolet radiation in the upper atmosphere and thence the determination of the ozone content of the atmosphere. A photographic method of observation was developed and instruments were distributed to suitable observers in many countries. Later, a photoelectric method was devised to facilitate the routine measurement of atmospheric ozone. Observations made by collaborators in many parts of the world have established the nature of the variation of ozone content with season and latitude, and have revealed close relationships between the amount of ozone, the development of atmospheric pressure at sea-level and certain meteorological characteristics of the atmosphere. Further advances are to be hoped for from an extension of international co-operation in prospect.

Emmanuel Swedenborg (1688-1772)

TO-DAY world-wide celebrations are being held to commemorate the 250th anniversary of the birth of the great Swedish man of science and theologian, Emmanuel Swedenborg, who was born in Stockholm on January 29, 1688, and died in London on March 29, 1772. His death took place at 26 Great Bath Street, Clerkenwell, and he was buried in the Swedish Church, Princes Square, Stepney, whence, however, his remains were taken to Sweden in 1908. He was the second child and eldest son of Jasper Swedberg (1653–1735) a preacher, poet and visionary, who became bishop of Skara. From an early age young Swedberg, a name he bore until he was ennobled in 1719, showed unusual talent, and after studying at the University of Uppsala in 1710 came to England. He also visited France and Holland and in 1716, two years after returning home, published his "Daedalus

Hyperboreus", a kind of repository of contemporary inventions and experiments. In the same year Charles XII made him assessor in the College of Mines. His writings from that time onwards, published and unpublished, ranged over the whole field of science. In 1721 he wrote his "Prodromus Principiorum Rerum Naturalium", in 1722, a work on geology, in 1734 published in three volumes his "Opera Philosophica et Mineralia", in 1741 his "Economy of the Animal Kingdom" and in 1744–45 his "Animal Kingdom", with which his course as a natural philosopher ended. In London in 1749–56 he published his "Heavenly Arcana" and this was followed by some two score of theological works. He himself made no attempt to found a sect, but his followers established "the New Church signified by the New Jerusalem in the Revelation" and 'Swedenborgians' are to-day found all over the world.

THE removal of Swedenborg's body to Sweden in 1908 was but a part of a movement for the recognition of his genius as a man of science. In 1901 Dr. Max Neuberger, of Vienna, gave an address to an assembly of German naturalists and physicians entitled "Swedenborg's References to the Physiology of the Brain", in which he pointed out how Swedenborg had anticipated many modern discoveries. Dr. Neuberger next addressed a communication to the Academy of Sciences of Stockholm in which he expressed his regret that Swedenborg's manuscript on the brain had not been published. A committee was appointed to investigate the matter. On May 29, 1903, Prof. Gustaf Retzius, the president of the Academy, presented a report on the investigation to the Congress of Anatomists at Heidelberg. This led to a further examination of the manuscripts, and Dr. Retzius proposed that the Academy should issue an edition of Swedenborg's scientific and philosophical works. Even before this, proposals had been put forward for the founding of a museum for the preservation of portraits, relics and other Swedenborgiana. Emerson wrote of Swedenborg: "He had great modesty and gentleness of bearing. His habits were simple; he lived on bread, milk and vegetables; he lived in a house situated in a large garden. . . . He is described, when in London, as a man of a quiet, clerical habit, not averse to tea and coffee, and kind to children. He wore a sword when in full velvet dress, and whenever he walked out carried a gold-headed cane. There is a common portrait of him in antique coat and wig, but the face has a wandering or vacant air."

Scientific Delegation to India

OUR correspondent, writing from Bombay on January 15, says: "Some sixty members of the scientific delegation to India, including the president, Sir James Jeans, embarked on the S.S. *Strathaird* at Bombay on January 15 for the homeward voyage. Of these, nearly all had made the whole or part of the tour in Southern India arranged to take place after the Congress in Calcutta. This tour embraced visits to Madras, Mysore, and Bangalore, which none would willingly have missed. After a hot journey south, Madras received the delegation with a very perfect day, during which the University gave a luncheon, and most of the delegates attended a garden party arranged by the city in honour of the Viceroy. The small but very attractive aquarium, and other points of interest, were visited. The wonders of Mysore will never be forgotten by the visitors. They were received as guests of the State throughout their too short sojourn and were shown many of the institutions which are there maintained by an enlightened Government, while when darkness fell they viewed with amazement the illuminated fountains at the great power dam on the Cauvery, and the blaze of lights from the city as seen from Chamundi Hill. At Bangalore the Indian Institute of Science and other institutions were visited, and the party was entertained to tea by the Dewan Sahib of Mysore.

"AT all three cities visited during this southern tour, as indeed at every city visited throughout India, members of the delegation have freely responded to the many calls upon them for lectures, and all, whether so occupied or not, have had constant opportunity for the renewal of contacts with old students now occupying responsible positions in the places visited, and for making new acquaintanceships with workers in their various fields of interest. The whole spirit of the visit has been one of mutual and practical help, and nothing has impressed us more than the immense interest of the community in the delegation, and especially that of the students who have thronged the lectures and incidentally demanded of us inconceivable numbers of autographs. The visit has been said, by many influential Indians, to have been a great event for India: certainly it has been so for the delegation."

Museums and the Research Worker

SOME aspects of recent criticism of ethnographical collections in the museums of Great Britain are considered on p. 179 of this issue of NATURE. It cannot be emphasized too frequently that the great national collections—the question under discussion cannot affect the smaller museums except in so far as they are prepared to specialize—being supported out of public funds, it is their bounden duty to perform a function of public utility; whether that may be, as is now generally required of them, that they should take their share in making efficient and supplementing the machinery of general education, or the more highly specialized function of assisting the research worker. To the latter rather than to an attachment to a traditional system must be attributed the classificatory organization which has been subjected to criticism. For it must not be forgotten that the great national collections, as well as the smaller ethnographical museums, some highly specialized, such as the Pitt-Rivers Museum at Oxford, the Museum of Archæology and Ethnology at Cambridge, or the Manchester University Museum, have been the laboratories for the scientific researches of the technologist in the broader sense, the student of material culture. It is upon this class of evidence that the archæologist, the ethnologist and the student of early culture generally so largely rely. In the modern museum building, however, the trend of development is to make provision for the worker in technological research by withdrawing the bulk of the material in which he is interested from public exhibition, while the public galleries are given over to the more striking objects or to those of most educative value to the public. Doubtless when more space is given to our great public collections, the same method of procedure will be followed, and the public galleries will then be devoted to regional methods of display, in so far as these may have approved themselves as the most effective for purposes of instruction.

Publication of Old Scientific Works

A SMALL committee, presided over by Prof. B. Nemeč, met at Prague on December 3 and 4 to study, on behalf of the International Organisation for Intellectual Co-operation, the possibility of publishing old scientific works. This question had been raised by Prof. Nemeč, on behalf of the Czechoslovak Research Council, and had been adopted as part of the plan of scientific work of the International Organization for Intellectual Co-operation, by the executive committee of the International Council of Scientific Unions, acting as a committee of scientific advisers. The committee at Prague unanimously agreed that it would be desirable to publish a number of manuscripts or works on the exact and natural sciences, printed copies of which are extremely rare or almost inaccessible. A series of this kind would show the common origins of modern scientific culture and would be of great value to all savants interested in the historical development of the sciences. Considering the strictly international character of the undertaking, the committee felt that it should be entrusted to the International Organisation for Intellectual Co-operation. Further, the series should not be confined to one branch of science alone and it should embrace all the periods in the development of science since the Middle Ages.

THE publications envisaged may be divided into two series: Facsimiles relating to very rare manuscripts or works containing engravings or illustrations indispensable for the value of such works; and reprints of fundamental classical works in the development of the sciences, copies of which are extremely rare or no longer obtainable, including manuscripts that have never been printed. The committee suggested the publication in facsimile of the following manuscripts in the order given: (1) "De Revolutionibus orbium coelestium", by Nicolaus Copernicus; (2) "De proprietatibus rerum", by Bartholomeus Anglicus (facsimile reproduction of the illustrations which appeared in all the editions, summary of each chapter of the original work, and a biography of the author); (3) "Micrographia", by Robert Hooke. In addition, the committee suggested the reprinting of the following very rare works and hitherto unpublished manuscripts in the order given: (1) "New System of Chemical Philosophy", by John Dalton; (2) a selection of letters from the scientific correspondence of Johannes Hevelius, astronomer and selenographer, the greater part of which is at the Bibliothèque Nationale, Paris; (3) "Opuscula Botanitii argumenti", by Rudolf Camerarius; (4) "De solido intra solidum naturaliter contento", by Nicolaus Steno; (5) "Origin of Species", by Darwin (a reprint of the first edition, 1859); (6) "Expériences pour servir à l'histoire de la génération des animaux et des plantes", by Lazaro Spallanzani; and (7) "Disquititio de sexu plantarum", by Linnæus.

Excavations in North Syria

AT the Friday evening discourse at the Royal Institution on January 21, Sir Leonard Woolley described "Excavations in North Syria". The object of the North Syrian Expedition has been to trace such relations as may have existed between Asia and the early Greek world, especially during and before the rise of the Cretan civilization. Two sites were chosen on the trade-route afforded by the Orontes valley. One was at al Mina, at the river mouth, one at Atchana in the Amk plain where the road debouches from the mountain range and runs across open country past Aleppo to Carchemish and the Mesopotamian centres. At al Mina, underlying the ruins of the crusading port of St. Simeon, there were found nine further strata giving a continuous record of commercial activity from 300 B.C. back to the beginning of the eighth century. During the fifth and fourth centuries Athens, in spite of the long-drawn crisis of the Persian wars, enjoyed a trade monopoly with Persia. In the sixth century B.C. the bulk of the trade was in the hands of the Rhodian manufacturers, but Corinth, Naukratis and Lesbos secured a certain amount of it and Cyprus was still selling goods in Asia although in greatly reduced measure. In the seventh century, judging by al Mina, Cyprus entirely controlled the market; of all the imported pottery found there scarcely a sherd is not Cypriote. This domination had come about quite suddenly. It was a natural result of the wealth of the Asiatic clientele that the al Mina merchants imported always the best wares that were to be obtained; from each manufacturing centre the finest quality was selected and the centre changed according as its level of production rose or fell.

THE earlier strata of al Mina have been eroded by the river; for the period preceding the eighth century we have to look at the second site. The topmost stratum at Atchana is dated by imported Mycenæan pottery to the twelfth century B.C. In the second stratum below this, dated to the 15th–14th centuries, there are the earlier Mycenæan wares side by side with a remarkable painted pottery which is undoubtedly local, in some aspects identical with the 'Hurrian' wares found on other sites, in others altogether novel in Asia but strikingly reminiscent of Knossos. The city in which this pottery occurs, and that beneath it, down to the Fourth Period, is Hittite; and there are Hittite inscriptions side by side with documents in cuneiform. In the Fourth Period Sir Leonard has begun to excavate a palace the architecture of which both in material and in style seems as essentially Cretan as does the painted pottery; objects in gold and ivory testify to its richness, and cuneiform tablets appear to show that it was a royal building and date it to the sixteenth century B.C. This year's season will be devoted to the clearing of the palace, and its results should certainly throw light on the connexions between Crete and the Syrian mainland.

British Archæological Investigation in France

On more than one occasion recently, French archæologists have expressed admiration for the methods of excavation followed in Great Britain on such sites as Maiden Castle and St. Albans, and at the same time have regretted that a similar procedure had not been introduced into archæological studies in France. In a recently published report (*L'Anthropologie*, 47, 5–6) of the proceedings at the last sitting of the Commission des Monuments historiques (Section de Préhistoire) reference is made to the concession to excavate the fortified site of Artus at Huelgoat (Finistère) granted by the Commission to the Society of Antiquaries of London, of which the direction will be in the hands of Dr. R. E. Mortimer Wheeler and Mr. R. Radford. The report goes on to add that while the antiquities discovered will naturally remain the property of France, a greater gain will be the experience thus to be acquired of methods of systematic investigation, of which archæologists in France have but a very faint idea, not only as regards the work of digging but also in regard to interpretation. through the co-operation of specialists, and the supreme excellence of the planning and photography, to say nothing of the preservation of the stratigraphic record. It is, perhaps, unnecessary to add that in this international exchange the gain of Great Britain will be no less in the acquisition of systematized evidence which may be expected to throw no little light on the relation of the cultures of north-western France and the west of Britain in prehistoric times—a relation which recent discovery suggests may have been even closer than has hitherto been anticipated.

International Telecommunications Conference at Cairo

Radio communication is essentially an international affair, and it is therefore necessary that it shall be conducted according to rules and conventions agreed to by all the principal countries in the world. The necessary regulations are drawn up by international conferences which are held at intervals of about five years and are attended by delegations from the administrations operating the radio services in the various countries. These conferences are organized by the International Telecommunications Union, with headquarters at Berne, Switzerland, the function of which is to co-ordinate telecommunication of all types, telegraph and telephone, cable, wire and radio. At the present time, world radio communication is being conducted under the Madrid Convention which was drawn up at the end of 1932.

On February 1, a new conference will be opened in Cairo with the object of revising the existing convention in the light of progress and developments in the past five years. During this period, the technical aspects of the various questions involved have been studied by international technical committees, such as the Comité Consultatif International des Radiocommunications (C.C.I.R.), which last met at Bucharest in May–June 1937. The general objective of these committees and of the Cairo conference is to revise the existing convention in such a manner as to place telecommunications on the most efficient and equitable basis for the world as a whole. On the radio side, considerable attention is given to the allocation of wave-bands among the claimants representing the various interests involved, which range from commercial services and defence requirements through broadcasting to various scientific and experimental interests. The Cairo Conference is expected to last from six to twelve weeks, and the application of the results may require a year or more to put into effect, so that ample time is provided for industry and the users of communications to prepare for such changes as may be involved.

British Snowfall Survey

At the first meeting of the International Snow Commission held in Edinburgh on September 14–16, 1936, members of the British group emphasized the importance of snowfall in the hilly districts of the British Isles, pointing out, also, that if the climate were to take a slightly colder turn the snowfall would become decidedly impressive over a large portion of the country. Out of this meeting there arose the formation of the Association for the Study of Snow and Ice, and among other activities of this body a scheme has been launched for extending our knowledge of snowfall in Great Britain from observations of the extent, duration and depth of snow-cover. It is thought desirable to begin systematic study with limited areas in such snowy districts as the Cairngorms, the Southern Uplands of Scotland and the northern Pennines, gradually extending the scheme to cover the whole of the country. It is hoped to investigate the permanent, semi-permanent and late-lingering snow-drifts in the Scottish Highlands, and the northern English and Welsh mountains, together with such important phenomena as the long-distance, mass-drifting of snow whereby quantities of snow in severe blizzards may pass out of the drainage basins into which, but for the wind, they would have fallen. The plan will thus supplement valuable information already being obtained from the rainfall stations of the Meteorological Office, and readers interested should communicate in the first instance with the chairman of the Ice and Snow Association, Mr. Gerald Seligman, at Warren Close, Coombe Hill Road, Kingston Hill, Surrey.

Pacific Entomological Survey

On November 2, 1932, a statement of the work and objects of the Pacific Entomological Survey was made before the Royal Entomological Society of London, as a result of which a resolution was passed unanimously inviting Dr. S. A. Neave to write and commend the work in the name of this Society, of which he later became president. On November 26 of the same year an appeal was issued in Nature (130, 802–3; 1932), and further generous support was, despite the depression, forthcoming from various sources in Hawaii and elsewhere. Then, in 1935–37, liberal grants through the trustees of the will of the late Viscount Leverhulme and through the British Museum (Natural History) enabled Mr. E. P. Mumford, director of the Survey, to accept Sir Edward Poulton's invitation to complete the present phase of the work in the Oxford University Museum, where Sir Edward's successor, Prof. G. D. Hale Carpenter, is extending the hospitality of the Hope Department. The work of the Survey is of interest to all countries the territories of which either surround or extend into the Pacific, for, as Dr. Neave points out in the letter referred to above, "a knowledge of the fauna of all the Pacific Islands may well be of the utmost value in the more cultivated and developed ones, in that it may give a clue to the origin of many of the local pests of the latter, and thus point to opportunities for devising their biological control".

The work of the Survey is already well advanced, and some 150 papers have been submitted for publication in Hawaii and elsewhere. It was originally proposed to prepare for publication a résumé and analysis of the findings of the Survey, and a discussion of the bearings thereof on the problems of distribution of insects in the Pacific, but it is becoming increasingly apparent as a result of the researches in Oxford that such an analysis will, to be of any value, have to take into account, not only the fauna of the islands of the Pacific, but also that of other islands. In reviewing (Nature, 130, 797; 1932) a manuscript copy of "Entomological Researches in the Marquesas Islands" (afterwards published in V^{e} Congrès International d'Entomologie, pp. 431–450, Paris, 1933), Dr. Hugh Scott referred to certain groups that are said to be absent from the Marquesas, and stated that the authors, Messrs. Mumford and Adamson, regarded these gaps in the fauna as strong evidence against the existence in past ages of extensive land areas in the Pacific, but, as Dr. Scott points out, some of these groups are also absent from the faunas of islands not of volcanic and purely oceanic origin. Furthermore, some of these groups that are thought to be absent from the Marquesas have been taken in supposedly oceanic islands elsewhere. Though Cicadas are unknown in the Marquesas, a remarkable genus has been described from Samoa, which island group Prof. Buxton considers to be oceanic. Caddis-flies and may-flies, supposedly absent from the Marquesas, have been taken in Samoa as well as in the 'crypto-oceanic' Canary Islands and Madeira, and froghoppers, which were not met with by Messrs. Mumford and Adamson in the Marquesas, are known from Tonga, Samoa, the Society Islands, and Rapa. In bringing these extensive studies to a focus in Oxford, and at Farnham House Laboratory by courtesy of Dr. Thompson, Mr. Mumford and his assistants have received every assistance and co-operation from specialists throughout the world. Correspondence concerning island faunas may be addressed to the Hope Department of Zoology (Entomology), University Museum, Oxford.

Progress towards Internationalism

The October–January number of *Science and Society* is devoted to a discussion of the conditions of progress towards internationalism. Prof. E. Jäckh, in an article on "The Changing International Relations", stresses the necessity of development into supra-national relations. Supra-national science has made possible and indeed necessary the organization of an international society. The tempo of such development, in which science shows the way, is determined by the extent to which humanity values technical civilization, science and their world-changing effect as bursting asunder the frontiers between peoples. Prof. H. J. Fleure contributes an article on "Society and Liberty" in which he shows that society must be studied ecologically with a deep realization that no one has the whole truth; we are all seekers, and the truth is far above us all. He urges that it is our duty, in the name of science, to plead for freedom of conscience not only as an essential for scientific thought, but also as the only way in which in the long run society can keep in touch with the ever-flowing changes in the world. "Anthropology and racialism" is the subject of an article by J. C. Trevor, who, directing attention to some of the inherent difficulties in the consideration of problems of race, points out the danger to world peace which the accentuation of racial disparities may offer if identified with nationalistic aspirations.

Adrian Stephen's article on "War and Emotional Development" discusses some difficulties in a supra-national authority and suggests that a hopeful line of progress lies in learning to regard countries or nations as pieces of machinery with definite functions for the promotion of human happiness rather than as idealized mothers and fathers. The application of science to political and international affairs at the present juncture is urged by C. A. Mace, in a thoughtful article "Planning Peace", to be less a matter of using specific material from the relevant social sciences than of infusing politics with some respect for the scientific spirit and the scientific point of view. Mr. Mace stresses the need for a system of publication, without fear or favour, of tested matters of fact, as essential to restore public confidence and to give intelligence to public judgment. R. H. Pender's survey of the political phases of Western Society leads him to the conclusion that any re-integration of society has to be achieved consciously and can only be tackled after an adequate idea of the nature of a society has been gained. This is in the first place a task for social science, since science alone has sufficient authority to get its conclusions adopted universally as a basis for action.

Science and University Teaching

AN article by Dr. W. H. George on "Science and University Teaching" in the *New University* of November, emphasizing the value of the widespread use of scientific methods in dealing with the social problems of to-day, points out that an education which includes one or more sciences does not necessarily foster scientific action. Even a knowledge of science up to university degree standard does not necessarily guarantee ability to think or act scientifically within the scope of the sciences studied. While, however, teaching is the best way of promoting the use of the scientific method, Dr. George points out that, in general, science but no scientific method is taught to science students and that scientific method, but no science, is taught to a small proportion of arts students and this teaching is separated from that of the student's main subject of study.

National Forest Park near Snowdon

A COMMITTEE was appointed by the Forestry Commissioners on March 31 last to advise as to the steps which might be taken to form a national forest park on their properties in the vicinity of Snowdonia. It has now issued its report on the "National Forest Park Committee" (H.M. Stationery Office, 1937). The Forestry Commissioners had expressed an intention of designating areas, such as the one here under consideration, 'National Forest Parks'. It is pointed out that this type of park has no affinity with the 'National Park' as described in the report of the National Park Committee. The area here in question is the Gwydyr Forest of about 18,000 acres. The Forest forms a fringe of the wild and open mountain land culminating with the Snowdon range with its large stretches of foothills and rough grass, heather and rock-strewn spaces. The central Snowdon region is mostly in private ownership. The land in Gwydyr Forest which has been, or will be, planted by the Forestry Commissioners comprises about three-quarters of the area and forms the lower slopes on the east and south-east of the Snowdon range, in which group of mountains is included the Glyders and Carnedd mountains. There are numerous roads, tracks and footpaths, many of which afford delightful walks, climbs and views. The district includes some of the finest mountain scenery in North Wales and attracts a very large number of holiday-makers in the summer. The larger part of the Forest is held by the Commissioners on long leases subject to certain reservations. Local hostels exist, and certain other facilities in this respect and camping facilities are recommended, it being suggested that Government be asked to provide funds for the Commissioners' use in these developments. Such funds should surely be obtainable from the region which will benefit by the provision of this national forest park.

Acquisitions at the British Museum (Natural History)

AMONG the specimens presented to the Department of Mineralogy of the British Museum (Natural History) is a collection of about three hundred rock and mineral specimens, made by Mr. H. St. J. B. Philby, between Mecca and Mukalla, during his last journey of exploration through West and South-West Arabia. The collection is not only of academic interest. There is evidence of the presence of oil in the richly bituminous limestones and oil-soaked shales outcropping in the neighbourhood of Shabwa, and farther north, near Jizan, Mr. Philby collected specimens of hæmatite, an important iron-ore. This mineral is also present in several quartz-reefs, of which he brought back samples. By his careful and complete field-records of each occurring type, Mr. Philby has brought to light a number of salient features in the geological structure of a region previously unknown to Europeans, and has made it possible to prepare an approximate geological map of the region through which he travelled.

Vital Statistics in Great Britain

ACCORDING to a return published by the Registrar-General, the birth-rate in England and Wales during the year 1937 is provisionally estimated at 14·9 live births per thousand of the population, and the crude death-rate at 12·4 deaths per thousand of the population. The number of deaths of children under one year, per 1000 live births, was 58. The birth-rate for 1937 is 0·1 above that for 1936, 0·2 above that for 1935 and 0·5 above that for 1933—the lowest on record. The crude death-rate is the highest recorded since 1929 and is 0·3 above that of 1936, an increase which is largely associated with the heavy influenza mortality of the first quarter of the year. The infant mortality is 1 below that of 1936, and only 1 above that of 1935—the lowest recorded.

Rheumatic Fever as a Protozoal Disease

DR. G. ARBOUR STEPHENS, 61 Walter Road, Swansea, referring to a recent Colonial Office Medical Report on the Falkland Islands, states that although the weather there is described as very damp and "permanent October" weather, and although the houses are damp, the soil acid, the food so poor that the school children wear dentures, and septic tonsillitis (due to *Streptococcus*) is so common, nevertheless rheumatic fever does not occur. This, he claims, supports the view that rheumatic fever is due to a protozoon (something like the malarial parasite), for the necessary insect carriers, such as harvest bugs, midges and fleas do not exist on the Islands.

Current Titles

WE have received the first part of a new monthly journal, *Current Titles*, published by Engineering Journals, 928 Broadway, New York, the subscription being 3 dollars yearly (4 dollars outside the United States). The journal gives the tables of contents of a large number of scientific, technical and engineering journals in English. We note that these include

Government publications, and that geology, physics, metallurgy and chemistry are well covered; biology is not dealt with, as there is a similar journal in this field. The new journal will serve a very useful purpose, since it gives at a glance the titles of papers in a wide field. The format is very convenient.

Fifth Glass Convention

THE fifth Glass Convention will be held at the Norbury House Hotel, Droitwich, on May 18–21 under the presidency of Mr. H. S. Williams-Thomas. This year will be an important one in the history of the British glass industry because in London the Society of Glass Technology has just concluded its twenty-first anniversary celebrations, and in April the *Daily Mail* Ideal Home Exhibition at Olympia will have glass as its outstanding motive. A subject which is engaging the attention of industrialists at the moment is the trade cycle, on which Mr. Harold Macmillan, M.P., will speak during one of the business sessions. Mr. Ronald Cartland, M.P., will give an address on "Recent Industrial Legislation". The presidential address will be entitled "Craftsmanship in Industry". Prof. W. E. S. Turner will lead the discussion on the presidential address. Of no less interest are the technical sessions arranged by the Society of Glass Technology, the subjects being "Glass Finishing Processes" and "Plastics and their Relation to the Glass Industry".

Announcements

SIR JOHN SNELL, chairman of the Electricity Commission, has been awarded the Faraday Medal of the Institution of Electrical Engineers. The Medal is awarded once a year either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the institution. Mr. Frank Gill, past president of the Institution, has been elected an honorary member of the Council of the Institution.

THE Messel Medal of the Society of Chemical Industry has been awarded to Prof. L. H. Baekeland, honorary professor of chemical engineering in Columbia University. Prof. L. H. Baekeland is the founder of the plastics industry and his own name is perpetuated in the well-known commodity 'Bakelite'. He was also responsible for the 'Velox' patents used in modern photographic industry. The Messel Medal is awarded every two years for meritorious distinction in science and its application to industry.

DR. E. W. RUSSELL has been appointed Goldsmiths' Company's soil physicist at the Rothamsted Experimental Station in succession to Dr. G. W. Scott Blair, who has been appointed head of the Dairy Chemistry Department at the National Institute for Research in Dairying, Shinfield, Reading. Dr. Russell studied soil science at Zurich under Prof. Wiegner and in Russia under Prof. Polynov; for the past few years he has been assistant in the Soil Physics Department, Rothamsted, and has published various papers on soil texture.

AT the annual general meeting of the Royal Meteorological Society on January 19, Dr. B. A. Keen, assistant director, Rothamsted Experimental Station, Harpenden, was elected president in succession to Dr. F. J. W. Whipple. Other officers elected include: *Secretaries*, H. W. L. Absalom, W. Dunbar, E. L. Hawke; *Treasurer*, W. M. Witchell; *New Members of Council*, C. E. Britton, Dr. R. F. Fox, Major H. C. Gunton, R. S. Read, Gerald Seligman and Dr. R. C. Sutcliffe.

THE following have been elected officers of the Royal Microscopical Society for the present year: *President*: J. E. Barnard; *Hon. Treasurer*: C. F. Hill; *Hon. Secretaries*: Prof. R. T. Hewlett and J. Smiles; *New Members of Council*: Dr. J. A. Murray, J. H. Pledge, T. E. Wallis and S. R. Wycherley; *Hon. Editor*: Dr. G. M. Findlay; *Hon. Librarian*: Dr. C. Tierney; *Hon. Curator of Instruments*: M. T. Denne; *Hon. Curator of Slides*: N. Ingram Hendey.

THE forty-first Bedson Lecture will be delivered by Prof. J. Kenner, professor of technological chemistry, University of Manchester, at King's College, Newcastle-upon-Tyne, on Friday, February 4. Prof. Kenner will take as his subject "Aliphatic Diazo Compounds".

PROF. BERNARD NOCHT of Hamburg has been awarded the shield of nobility of the German Reich.

PROF. RICHARD KUHN, director of the Kaiser Wilhelm Institute for Medical Research at Heidelberg, and Dr. Ernst Spath, professor of chemistry at Vienna, have been elected honorary members of the Société de Chimie Industrielle of Paris.

PROF. MAX EUGLING, who is well known for his climatic and hydrological researches, has succeeded Prof. Grassberger as chief of the Institute of Hygiene of the University of Vienna, where he has been assistant for the last thirty years.

THE second Darling prize of the League of Nations for original work on malaria published during the previous five years has been awarded to Prof. N. H. Swellengrebel, professor of tropical parasitology at Amsterdam, and will be awarded to him during the Third International Congress on Malariology in September 1938.

THE Association for Education in Citizenship has arranged a secondary school conference on methods of training for the responsibilities of citizenship, to be held at Morley College, Westminster Bridge Road, London, S.E.1, on March 4–6. Applications to attend the conference, accompanied by a fee of 5*s*., should reach the secretary of the Association, 10 Victoria Street, London, S.W.1, not later than February 5.

Letters to the Editor

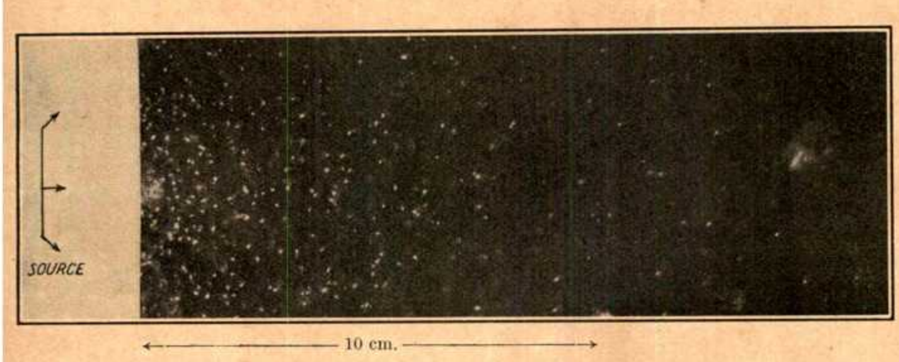
The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 207.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Nuclear Transformation by *K*-Electron Capture

THE theoretical expectation that a nucleus which emits positive electrons may, as an alternative mode of transformation, change by capturing a *K*-electron, was recently demonstrated experimentally by Alvarez[1], who was able to detect by means of a counter arrangement the fluorescent X-radiation which follows *K*-capture. Earlier experiments by Jacobsen[2], using an active isotope of scandium in an expansion chamber, had not shown any evidence of such fluorescent radiation. Alvarez's observations were made on titanium which had been bombarded by fast deuterons. Walke[3] had previously shown that one of the products of the bombardment is an isotope of vanadium, of mass number 48 and half-life 16 days, which emits positrons and thus transforms to ^{48}Ti. Alvarez concluded from his experiments that ^{48}V also transforms to ^{48}Ti by the capture of a *K*-electron, the two modes of transformation being about equally probable.



We have recently been able, through the kindness of Mr. Walke, to examine, in the expansion chamber, the activity of a specimen of titanium which had been bombarded by fast deuterons about five months ago. (This source was activated in the Radiation Laboratory, Berkeley, and was a gift to Mr. Walke from Prof. E. O. Lawrence.) The photographs obtained showed a number of tracks due to negative electrons, but very few due to positive electrons. When a magnetic field was applied to bend away these electrons, a large number of very short tracks was observed. These tracks show that a soft X-radiation is emitted from the titanium specimen, indicating, in a striking way, a *K*-capture transformation. The energy of the photo-electrons produced by the *K*-radiation of titanium (or of a neighbouring element) is only about 4,000 volts, so that their tracks appear as spots in the photographs. In the photograph reproduced here there are about 300 of these short tracks.

The photographs show the decrease in intensity of the radiation due to absorption in the gas of the chamber. This gas was oxygen at a pressure of 66 cm., which for titanium *K*-radiation has a linear absorption coefficient of about 0·07 cm.$^{-1}$. Preliminary counts of the spots in photographs taken with a collimated source, to avoid errors due to the limited depth of focus, gave an absorption roughly in accordance with this, indicating, actually, a parent atom of atomic number 21 ± 1 (Ti = 22). Further experiments will enable us to decide definitely the atomic number of the element responsible for the radiation.

The noteworthy feature of this example of *K*-capture is its large probability compared with that of the alternative process of positron emission. Indeed, unless positrons of very low energy are emitted, this ratio is of the order of 1000 : 1. Even this estimate assumes that the few positrons observed represent the same nuclear transformation. This may well not be the case, and it is not unlikely that the transformation by positron emission is energetically impossible (its threshold being about 2 mc^2 higher than that for *K*-capture).

In Alvarez's experiments on newly activated titanium, the number of *K*-captures was approximately equal to the number of positrons from ^{48}Ti. The latter decays with a period of 16 days and would thus have now about 1/1000 of its initial activity. The fact that we find about 1 positron for every 1000 *K*-captures is not inconsistent with Alvarez's results if we assume that the positrons are due to ^{48}Ti and the *K*-capture to a nucleus with a very long period. We should also mention that the recoil electrons produced by the γ-rays from the present source bear a much smaller ratio to the fluorescent quanta than in Alvarez's experiments, indicating that the bulk of the initial γ-ray activity is not associated with the *K*-capture process. Further observations will be made to elucidate the origin of the various radiations emitted by the source.

Altitude Effects in the Red Part of the Auroral Spectrum and the Two Types of Red Auroras

IN a previous note in NATURE[1], I described observations made at Oslo of an auroral display which showed red upper limits, while the lower part had the ordinary greenish-yellow colour. Spectroscopic observations gave an enormous enhancement of the red oxygen line 6300 with increasing height. In a later paper[2], I described quantitative measurements of spectrograms corresponding to auroras of ordinary colour, which also gave a considerable enhancement of the red line 6300 with increasing altitude. It became a matter of importance to make further measurements in order to see if the altitude effect on the red line was a general occurrence.

During auroral displays which were observed at Oslo on the two nights of October 11–13, 1937, I obtained on panchromatic plates four pairs of spectrograms. For each pair the spectrograms were taken as quickly as possible in succession, one from the lower, the second from the upper limit of the auroral streamers. Photometer curves of the spectrograms covering the red part and the green line 5577 are shown in the accompanying illustration. The first pair, I, was taken on the evening of October 11, the other three pairs II, III, IV during the following night.

Although the relative intensity of the red line is very different for different pairs, we find that *for each pair the relative intensity of the red line increases as we pass upwards from the lower to the upper limit.* By means of an intensity scale taken by means of a light source of known intensity distribution, we found the following intensities (I_r) of the red line relative to the green one :

Pair	I_r (upper)	I_r (lower)	$\frac{I_r \text{ (upper)}}{I_r \text{ (lower)}}$
I	2·74	1·15	2·38
II	0·82	0·60	1·37
III	0·75	0·36	2·08
IV	1·07	0·34	3·15

Mean, 2·25

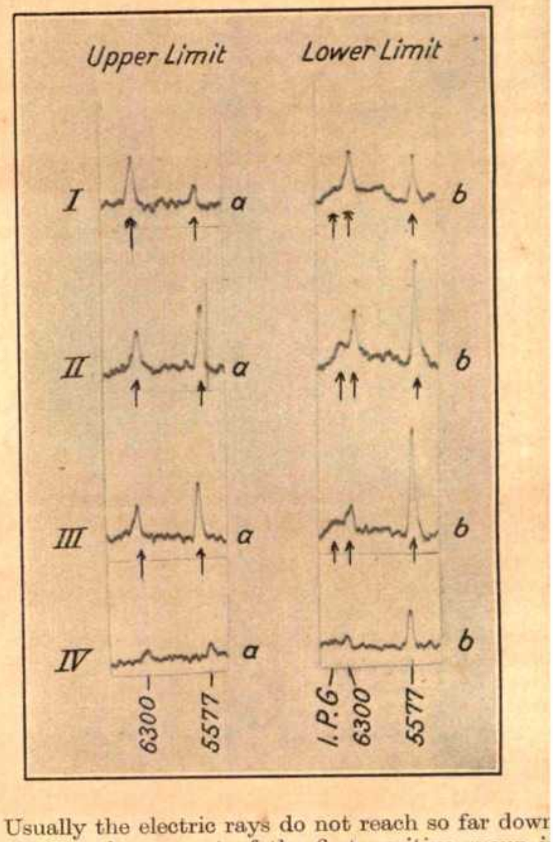
On an average, the relative intensity of the red line at the upper limit is 2·25 times that at the lower.

The numbers also confirm the result previously described[2] that the red line 6300 may obtain an intensity considerably greater than that of the green line, a result which shows that the $^1D_2$-state is excited by a certain process, which acts independently of that which excites the $^1S_0$-state, and which results in the emission of the green line.

The photometer curves for the lower limit all show distinctly the bands of the first positive group, while these bands are absent on all the curves corresponding to the upper limits showing the existence of a pronounced altitude effect of the first positive group, and in such a way that its intensity relative to that of the green line *increases as we pass downwards in the auroral region.* The altitude effects of the red line 6300 and of the first positive group have an interesting bearing on the two types of red auroras called A and B.

As I have shown, the red colour of type A is due to the enhancement of the red line 6300, which is particularly prominent during sunspot maxima and when the atmosphere is exposed to sunlight.[3] *The altitude effect of this line means that this type of red aurora has a tendency to be more intensively red towards the upper limits of the streamers.* The enhancement is shown to be due to an excitation process which brings the O-atom directly to the $^1D_2$-state, and this process is associated with some component of the atmosphere formed by the action of short-wave radiation from the sun. This component is probably ozone, and the $^1D_2$-state is excited through collisions between ozone molecules and nitrogen molecules in the metastable $A(^3\Sigma)$-state (cf. ref. 2).

Type B is characterized by an intense red colour along the *lower border* and was shown to be due to the enhancement of the first positive group, which is particularly pronounced when the aurora reaches a very low altitude. The results given in this note show that the enhancement is not restricted to regions near the lower limit, but *the first positive group shows a gradual enhancement as we pass from the upper limit downwards.*



Usually the electric rays do not reach so far dowr that the enhancement of the first positive group i sufficient to give the aurora a red lower border. A weak reddish lower border is fairly frequent, bu auroral bands with an intense and fairly broa red lower border are very rare and *seem to be mos frequent at times of sunspot minima*[4], showing that th electric rays obtain the greatest maximum energ at sunspot minima.

Origins of the Zodiacal Light

I refer to an important paper[1] by Prof. H. P. Robertson of Princeton, tracing out the effects of the Poynting principle of suction of fine orbital dust or gas into the sun or other strongly radiating star. It concerns me directly as in an amendment of the numerical factor for the reprint in Poynting's "Collected Papers" I inadvertently doubled the final value by adding the effects in the two frames of reference, that of the sun and that of the orbital particle, instead of taking them as alternative.

There could not be a permanent zodiacal light at all unless the particles that deflect it were sustained against falling into the sun, and that could only be by an orbital motion of planetary type for each particle, whose centrifugal influence holds it up against gravitation to the sun. The perhaps unexpected result is here involved that the rather thick disk around the sun, extending beyond the earth's orbit, which shines permanently throughout astronomical times, must be a residue of the original whirling solar nebula, which its presence indeed goes far to establish: for it can scarcely be conceived as formed by ejection of particles nearly tangentially from the sun's surface. Perhaps this arresting conclusion may not really be unfamiliar: Poynting had possibly known of it. The radiation incident from the sun exerts according to his principle a dynamical retardation which gradually converges each orbit spirally into the sun in a time not great on the astronomical scale, provided, however, the particles are not large compared with the wave-length of the radiation. This gradual subsidence demands a renewal from outside, in a steady stream, which is more rapid and so less dense for the smaller particles or gaseous atoms and ions. The particles must not collide as in a gas, else all would be broken up soon, and the gas ultimately sustained otherwise as a close-fitting atmosphere in Maxwellian manner.

Thus we are led to contemplate a nebula surrounding the sun, which has now become of the type of the rings of Saturn, but enormously less close packed. This favouring paucity of collisions is reasonable if only on account of the extreme tenuity of the distribution, like that in a comet's tail, the mean distances of neighbouring particles being comparable with miles. The mode of slow subsidence of a gaseous rotating nebula of this non-colliding type would perhaps be an interesting subject for mathematical analysis after the manner of the Saturn ring theory, conceivably even connecting up with a distribution of atoms not entirely negligible throughout the depths of space.

The immediate cause of this note is, however, a recent announcement from the MacDonald Observatory in Texas by C. T. Elvey and P. Rudnick[2] that the zodiacal light is ordinary reflected sunlight and shows no sensible proportion of a Stokes-Rayleigh scattering such as produces the blue sky. This shows, as they remark, that the particles which mainly deflect it have dimensions of the order of several wave-lengths at least. We note here in confirmation that by the Poynting analysis, smaller particles would, as *supra*, be sucked into the sun far more rapidly and be gradually winnowed out, more rapidly the nearer the sun, and therefore for given influx from beyond the replenishing stream would have far smaller density: the distribution of the larger particles would, in fact, require little replenishment, but could scarcely extend out indefinitely.

Diffuse nebulæ are held likewise to shine by illumination from blazing stars located in front of them, because they send the same kind of light; but for them the sideway scattered bluer light would have little chance of being important. No inference as to size of particles in these nebula would thus arise. This perhaps clears up the general question of colour in nebular cosmogony. The inference from colour as regards the zodiacal light would likewise be vitiated if the effective length of the source that is in the line of sight is large compared with distance of that line from the sun, which may be not improbable. But however that be, the Poynting dynamical train of reasoning here presented for the solar nebula would remain firm.

The Liquid State of the Primitive Earth

It has often been suggested that the earth must have been in a liquid state at an epoch near the very beginning of its formation. I wish to give an argument which confirms this view. If we suppose that the earth was originally in a gaseous state, we can imagine a model, which we call the globe, defined as a polytropic gas sphere of mass 6×10^{27} gm., equal to the present mass of the earth. Assuming (following Jeffreys) that the central temperature must have been equal to the effective temperature of the sun at the time of formation, that is, about 6000° K., and considering the polytropic indices $n = 3$, 1 or $\frac{1}{2}$, one finds a radius of $2{\cdot}2 \times 10^{10}$, $1{\cdot}28 \times 10^{10}$ or $1{\cdot}24 \times 10^{10}$ cm. The smaller values of n correspond to a lower compressibility than is generally assumed for the stars (Eddington). The values of the density are such that the material of the globe is very nearly a perfect gas. The pressure and temperature in the globe can then be calculated from Emden's tables, as functions of the distance from the centre.

On the other hand, by means of the Clapeyron-Clausius law, one can estimate the boiling temperature of the metallic vapours as a function of the pressure, and consequently as a function of the distance from the centre in the globe.

If the polytropic temperature and the boiling temperature of iron (the most abundant metal) are plotted against this distance, it is found that in a thick outer layer of the globe, the conditions are such that the iron must condense into liquid metal and consequently precipitate in drops towards the centre. Any other reasonable choice of the characteristics of the globe such as would give a good model of the earth leads to the same conclusion. This condensation may be considered as spontaneous. The thickness of the layer is about $\frac{3}{4}$ of the radius of the globe for $n = 3$, and about $\frac{1}{2}$ for $n = 1$ and $n = \frac{1}{2}$.

This conclusion provides an explanation of the occurrence of the iron core which is generally regarded as occupying the centre of the earth.

A full account of this theory will appear shortly in the *Archives des Sciences physiques et naturelles*.

Westward Extension of the Ranikot Sea

IN a previous letter[1] I showed that the Ranikot (Palæocene) Sea of India must have extended over the whole length of the Himalayas, from eastern Tibet to Waziristan. More recently, some interesting fresh evidence has been found regarding the extent of the Ranikot Sea; for Mr. A. G. Davis, who is working for the Anglo-Iranian Oil Company, informed me that he had found Ranikot fossils in collections made by Dr. J. V. Harrison of that Company from a section near Shamshir-i-Quli (lat. 33° 30′ N.; long. 47° 10′ E.) on the western borders of Persia.

These collections Mr. Davis has since shown to me, and I have been able to confirm his opinion, identifying the following species as present: *Nummulites nuttalli* Davies, *N. thalicus* Davies, *Operculinoides* cf. *sindensis* Davies, *Miscellanea stampi* Davies, *M. miscella* D'arch. and Haime, *Sakesaria* cf. *cotteri* Davies and *Alveolina globosa* Leymerie. The thickness of Upper Ranikot beds at Shamshir-i-Quli is at least 500 feet; and the succeeding less fossiliferous beds, with forms which I referred to *Alveolina lepidula* Schwager, *A.* cf. *oblonga* D'Orbigny and *Orbitolites* cf. *complanatus* Lamarck, would seem to be of Laki age. Although true Ranikot fossils have not yet been found in any other collections received by Mr. Davis, the existence of the Ranikot at Shamshir-i-Quli is unquestionable.

The occurrence is worth recording, since Ranikot beds have never before been certainly located much farther west than long. 68° E. Taken in conjunction with my discovery[2] last year of an abundant Upper Ranikot fauna in Sir Henry Hayden's collections from Kampa Dzong, due north of Calcutta, this last discovery shows that the Upper Ranikot Sea extended in an east-to-west direction from the vicinity of Lhasa to that of Bagdad.

I am indebted, for permission to publish these facts, to the courtesy of the Anglo-Iranian Oil Company.

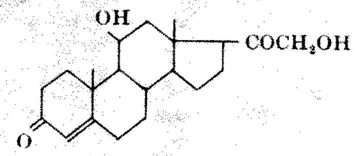
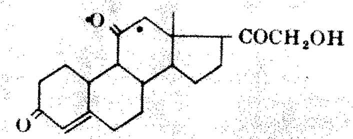
Chemical Structure of Corticosterone

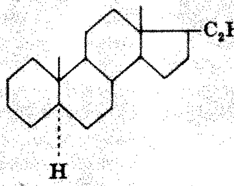
THE adrenal gland produces a hormone which is essential to life. During the last two years, several workers have succeeded in isolating, from purified preparations of the cortical hormone, a number of crystalline compounds. Among these substances corticosterone and dehydro-corticosterone possess the greatest biological activity. The structures (I) and (II) were proposed for corticosterone and its dehydro-derivative[1,2]. These formulæ were not definitely proved, but were chiefly based on the assumption that corticosterone might possess a constitution similar to some of the above-mentioned compounds, which have been isolated from the adrenal gland and which have been found to contain one more atom of oxygen in their molecules. These substances, which can be designated as the C_{21}-O_5-group, contain the sterol ring-system since they can be converted into the hydrocarbon androstane[3]. The suggestion that corticosterone contains the same ring-system has so far not been supported by any experimental evidence.



(I)
Corticosterone



(II)



(III)
Allo-pregnane

By means of a series of reactions, the details of which will be published in the *Helv. chim. Acta*, corticosterone can be transformed into the hydrocarbon allo-pregnane (III) (m.p. 84°, $[\alpha]_D^{21} = +12\cdot7°$ in chloroform). The same hydrocarbon was also obtained by a Clemmensen reduction of allo-pregnane-dione-3·20[4]. This evidence appears, therefore, to prove the presence of a steroid structure in corticosterone.

Treatment with Ascorbic Acid of the Plasma of a Fowl affected by Erythroblastosis

IN the course of researches aiming at investigating the nature of the virus of aviary erythroblastosis, the following observations were made.

By adding to the plasma (plus sodium oxalate) of a fowl seriously affected by erythroblastosis (O. G. strain which we owe to the kindness of Prof. Oberling) ascorbic acid in determinate proportions, a turbidness was noticed in the plasma itself which, after having been kept in the ice-chest for some hours, became transformed into a precipitate. 0·1 gm. of ascorbic acid was dissolved in an 8 per cent sodium chloride solution. This solution was added to the plasma *as soon as the ascorbic acid was dissolved.* The final concentration of ascorbic acid in respect to the plasma was 1 : 150.

The following tests were made:

(1) Comparison of the activity of the plasma injected immediately after the ascorbic acid had been added with the same plasma not treated. *It was seen that the activity was not appreciably modified.*

(2) Comparison of the activity of the two fractions obtained from the plasma after treatment with ascorbic acid; kept in the ice-chest for three hours and centrifugal separation of the precipitate from the liquid above it. (The precipitate was washed on the surface with saline solution.)

Supernatant fluid	Precipitate
Animals inoculated	Animals inoculated
(1) died of erythroblastosis after 9 days	(1) survives
(2) ,, ,, ,, ,, 12 ,,	(2) ,,
(3) ,, ,, ,, ,, 14 ,,	(3) ,,
(4) ,, ,, ,, ,, 17 ,,	(4) ,,

(3) Comparison of the activity of the fraction obtained after treatment of the plasma with ascorbic acid and elimination of the precipitate in the way mentioned above, with the same plasma not so treated.

Plasma (+ oxalate) not treated			Ascorbic acid plasma supernatant fluid		
Animals treated	Positives	Average time of survival of positives	Animals treated	Positives	Average time of survival of positives
21	15	19 days	21	19	15 days

It seems, therefore, that the activity of the plasma treated with ascorbic acid (contrary to the results obtained by Claude[1,2] by acidification with other acids of watery extracts of Rous's sarcoma) remains altogether in the supernatant fluid; and indeed, the activity seems in some degree to be increased in respect to the normal plasma.

Other researches are being carried out with plasma of fowl affected by erythroblastosis brought, by means of lactic acid or galacturonic acid, to the same *p*H, so as to ascertain whether in reality the elimination of an inactive substance from the leukæmic plasma and its successive activation is, as would seem from purely preliminary observations, the consequence of an elective action on the part of the ascorbic acid itself.

Role of Manganese in the Biological Synthesis of Ascorbic Acid

SPECULATION on a possible explanation of the difference in ascorbic acid contents of different plants led me to the idea that this difference may be due to the activating influence on the synthesis of ascorbic acid by plants of some mineral or minerals which are not detectable by ordinary analytical methods. A close study of the paper by Boyd and De[1], who have made a spectrographic analysis of a number of vegetable and animal products, revealed the fact that the manganese lines are very prominent in those vegetable products and animal tissues which are generally rich in ascorbic acid content. This led me to the investigation of the role of manganese in the synthesis of ascorbic acid by plants and animals.

By germinating Bengal gram (*Cicer arietinum*) in distilled water and in dilute manganese sulphate solutions containing manganese equivalents of 1 in 10^6, 1 in 10^5 and 1 in 10^4 for six days under identical and sterile conditions, it has been found that the ascorbic content of gram germinated in dilute manganese solutions is higher than that of gram germinated in distilled water, the respective amounts synthesized being 63·7 mgm., 75·5 mgm., 86·6 mgm. and 84·7 mgm. per 100 gm. of the original dry grams. The ascorbic acid assay was made by a modified Tillmann method after reducing the dehydroascorbic acid in the extracts with hydrogen sulphide. The germination was better in 1 in 10^6 and 1 in 10^5 manganese solutions and more stunted in 1 in 10^4 manganese solution than in distilled water.

Fuller details of this and experiments on animals which are in progress will be published elsewhere.

Absorption of Carotinoids from the Human Intestine

IT is generally supposed that, for human beings, carotene of vegetable origin is the principal source for vitamin A. If this is true, it is important to know the absorbability of leaf carotene. We have investigated this on two healthy male adults (namely, ourselves).

Test dose			Excretion in fæces			
	carotene	xanthophyll	carotene	%	xanthophyll	%
50 gm cooked spinach	1080γ	3675γ	1017γ	94	2478γ	67
50 gm. cooked spinach + 30 gm. lard	1660	4805	1573	95	3893	81
100 gm. cooked carrots	5700	370	5643	99	163	44
β-carotene dissolved in oil	1056		437	41		

For one to two weeks a diet was followed which was very poor in carotinoids (bread, rice, lard, meat, Marmite and 50 mgm. ascorbic acid daily). Then the excretion of carotinoids in the fæces was determined before and after intake of a test dose of vegetables containing a known quantity of carotinoids. The fæcal carotinoids were extracted with alcoholic potash, shaken out with peroxide-free ether and after evaporation of the ether dissolved in petroleum ether. The carotinoids were estimated colorimetrically with the Zeiss stepphotometer after chromatographic analysis according to Tswett with activated aluminium oxide (Brockmann).

While on this diet, 6–10γ carotene and 57γ xanthophyll per 20 gm. fæces were excreted. In the accompanying table the results are summarized of the determinations of the excretion above this level after intake of different test doses.

From these data it follows that nearly the total amount of vegetable carotene was excreted. Much better absorption took place when the carotene was dissolved in oil. Vegetable xanthophyll was absorbed to a greater extent than carotene.

Experimental details and a discussion of the facts from a dietetical point of view will appear elsewhere.

Vascular Supply of the Pedicel and the Ovule in Species of Dilleniaceæ

THE vascular anatomy of the flower in many families of plants has been studied in recent years; but the family Dilleniaceæ has escaped attention. For this reason the floral anatomy of *Dillenia indica* Linn., *Wormia triquetra* Rottb. and *Wormia Burbidgei* Hook. has been investigated. The study has brought to light a number of interesting points, but the vascular supply of the pedicel and the ovule particularly has been found to be very unusual.

The pedicel in angiosperms normally shows in a transverse section either a complete ring of xylem and phloem or a ring of collateral vascular bundles surrounding a central pith. In these plants it has been found to show, through its greater length, several rings of vascular bundles. In *Wormia triquetra* there are five such rings arranged again in a ring-like fashion on the periphery of the pith (Fig. 1).

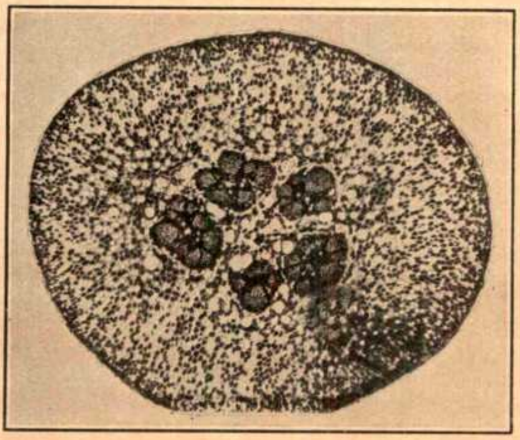

Fig. 1.
TRANSVERSE SECTION OF THE PEDICEL OF *Wormia triquetra*.

Each ring consists of 7–10 collateral vascular bundles with endarch protoxylem. In *Wormia Burbidgei* there are 8–10 rings; in *Dillenia indica* there are five such rings of vascular bundles. The pedicel thus in every case shows polystelic structure. Such a condition is not known in the flowers of any other angiosperms.

The ovule in angiosperms is generally supplied by a single vascular trace which travels up the raphe and ends at the chalaza. Rarely it may also penetrate the nucellus and reach the chalazal end of the embryo-sac. Exceptions to this condition are known only in some Amentiferous families, in which the ovular trace divides in the chalaza and sends branches to the integuments. In the above-mentioned Dilleniaceæ quite a new modification of the ovular vascular supply is seen. The ovular trace does not run unbranched up to the chalaza. It divides repeatedly during its course. About one third the way up, it bifurcates; the two branches divide again and then again. Ultimately all of them anastomose to form a plate of vascular tissue just at the base of the nucellus. The exact situation is shown in Fig. 2, which is a reconstructed diagram of the vascular supply of the ovule from a series of transverse and longitudinal microtome sections. Like the vascular supply of the pedicel, such a behaviour of the ovular trace has not been recorded for any other flowering plants.

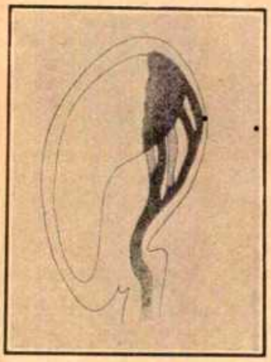

Fig. 2.
DIAGRAM OF THE VASCULAR SUPPLY OF THE OVULE IN *Wormia triquetra*.

The material for the investigation has been supplied by Prof. A. C. Joshi, and I am much indebted to him for suggesting the investigation and for guidance during its progress.

Genetic Control of a Morphogenetic Substance in *Drosophila melanogaster*?

STURTEVANT[1] has shown by the study of elimination mosaics involving an X-chromosome carrying the 'gene' Bar (reducing the number of facets in the eye of *Drosophila melanogaster*) that "the presence of tissue that is genetically 'not-bar' in some manner induces the formation of facets in tissue that is genetically bar and that would not normally have developed facets". The obvious conclusion was that these facts had to be interpreted "in terms of some influence that is intercellular in nature".

Transplantation experiments of Beadle and Ephrussi[2] have shown that Bar eyes, contrary to wild type eyes, do not produce the 'vermilion substance' required in the pigment formation of wild type. Unpublished results of Beadle and Ephrussi seem to indicate that several other genes influencing the size and the shape of the eye, such as Lobe or eyeless, partly or totally inhibit the production of the 'vermilion substance'. It was thought, therefore, that the vermilion substance and a '*facet-forming substance*', suggested by Sturtevant's experiments, might be developmentally and, possibly, chemically related. Consequently, experiments were performed in which Bar larvæ have been supplied with *Calliphora* extracts rich in vermilion substance[3]. The flies were raised at a constant temperature ($25 \pm 0 \cdot 1°$ C.). Three different concentrations of nitrogenous extract were tested: 4, 8 and 16 per cent.

The results of the experiments are very clear, especially in the case of the highest concentration, where the eye size shows an obvious increase. Some facet counts have been made; the following table summarizes the results of the counts made on males only :

	Observed facet numbers	Mean
Control	102, 97, 111	103
4 per cent extract	124, 134, 107, 120, 236	144
8 „ „	294, 211, 175, 337, 205	244
16 „ „	480, 486, 502, 4183, 89	455

(Among the treated females the observed maximum number of facets has been so far 382, as compared with the mean value of 85 in control females. Several heterozygous (*ClB/lz*) females have been observed: here the maximum facet number was 619 against 303 in the untreated control.)

It is clear that in these experiments the facet number has gradually increased up to about five times that of the control flies. There is considerable variation in the facet number within each experiment, which corresponds, in our opinion, to the variation of age of the larvæ at the time of treatment (in these experiments the age of the larvæ has been controlled only within 24 hours).

We interpret the above results as indicating that the extracts used contain a special morphogenetic (facet-forming) substance, the action of which is under genetic control.

The findings of Muller, Prokofjeva and Kossikow[4] and of Bridges[5], according to which the Bar effect is due to a small duplication, constitute a point of additional interest.

New Method for the Storage of Nematode Larvæ

THE following method of storing the infective larvæ of parasitic nematodes has been used at this Laboratory during the past twelve months and has proved to be very satisfactory. It has several advantages over the old method of storing in shallow water or in the fæces culture medium ; it is clean and convenient, it requires a minimum of special apparatus, it lends itself admirably to proper indexing, it makes a tremendous saving in storage space and is very favourable to the longevity of the larvæ.

After having been drawn off from the Baermann's separation apparatus, the infective larvæ which are intended for storage are flooded, in a small amount of water, on to one or more 9 cm. wide filter papers (Whatman No. 42) standing on several thicknesses of blotting paper. As soon as the excess water has soaked into the blotting paper, the wet filter papers are taken up and placed on a second pad of several thicknesses of blotting paper, where they are allowed to remain for from fifteen to twenty minutes, until all of the wetness has soaked away. Controlled observations have shown that the optimum point for the most successful storage of the larvæ lies somewhere between the time of the disappearance of the shining wetness, and the first signs of cockling of the filter paper, due to dryness at the edges. This point is reached in between fifteen and twenty minutes after the wet filter paper has been placed on the second pad of dry blotting paper, the required time varying with the temperature and dryness of the atmosphere of the laboratory.

The moist filter papers (with particulars of the larvæ written on the back) are now placed face to face in a 9 cm. wide petri dish, a piece of adhesive tape is fastened round the dish, between the lid and the bottom, to prevent evaporation, and the whole is put away in a cool room at 36–40° F.

When larvæ are afterwards required for any purpose, one or more filter papers may be taken out of the petri dish or, if only few larvæ are wanted, part of a filter paper may be cut off with a pair of scissors ; the paper is then placed, larva-side downwards, in a small amount of water in a petri dish or watch glass, when the larvæ quickly leave the paper and sink to the bottom of the vessel clean, and completely free from the debris that usually comes through the Baermann's apparatus along with the larvæ.

The method is also suitable for the transit of larvæ through the post, when the moist filter papers carrying the infective larvæ may be rolled up and placed in a test tube which is plugged with a tightly-fitting rubber stopper or treated in any other way which will prevent the evaporation of moisture from the filter paper.

The success of this method presumably depends upon the immobilization of the larvæ (through lack of actual wetness) and the provision which it makes for free contact with air in a water-saturated atmosphere. Examination of test cultures of trichostrongyloid larvæ stored in this way more than twelve months ago, show that 91 per cent of the larvæ are still alive and active. But apart from the convenience and efficiency of the method, the saving of storage space is enormous ; it is possible to store some five hundred cultures of larvæ in the eleven petri dishes held by an ordinary copper petri-dish container, which only takes up some 9 square inches of shelf room, whereas by the old fæces culture-medium storage previously used here that number of cultures would take up no less than 31 square feet, unless placed specially in petri dishes in the copper containers above-mentioned, in which case it would take up more than 3 square feet.

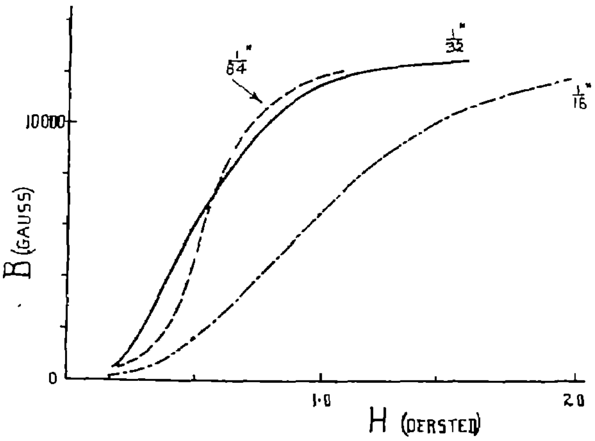
Magnetic Quality of Iron Wire as Influenced by the Diameter

IN a previous note[1] test data were given which showed how the permeability of nickel wire could be notably increased by surface treatment.

In the accompanying graph are given the magnetization curves for Armco iron wires of diameters 1/64 in., 1/32 in., and 1/16 in., respectively. The curves were obtained after each wire had been heated to 1200° C. in a stream of hydrogen until the permeability had reached a maximum value. From these and other test data it is inferred that :

(i) There is one diameter for which the permeability has the highest value, and the permeability falls off rapidly as the diameter is increased or decreased from this critical value. The critical diameter for Armco wire is about 1/50 in., in which case the permeability is about 15,000. For a wire of 1/100 in. diameter the permeability is about 12,000 and for a wire of 1/8 in. diameter it is only about 4,000.



(ii) There is a surface layer of the wire which is magnetically harder than the core, and this surface layer has a dominant influence on the magnetic quality of wires of small diameter.

(iii) By coating the wire with suitable material and afterwards heat treating, the magnetic quality may be controlled over a wide range. On one hand, the permeability may be increased and the coercive force diminished, and on the other hand, the permeability may be decreased and the coercive force increased. For example, it has already been shown that when nickel wire has been copper plated and then heat treated, the permeability is notably increased.

Similar tests have shown that there is also for nickel wire a critical diameter which gives maximum permeability.

Full details of these investigations are now in course of preparation for publication elsewhere.

Nomenclature of the Seasons

IN a recent letter to NATURE[1], Dr. John R. Baker proposes a new nomenclature of the seasons. The eight new names formed by him (boredune, borepheuge, notodune, notopheuge; homodune, homopheuge, heterodune, heteropheuge) are to make good the lack of denominations for periods longer than a month and independent of the geographical situation of the place where the speaker is living or of which he is speaking. I believe, however, that the introduction of eight new scientific terms of Greek extraction is quite unnecessary for this purpose.

Dr. Baker says that a statement like "in south-west Ceylon winter is the hottest season" is absurd—which it is obviously *not*, for the speaker is, of course, thinking of the winter to which he is accustomed, that is of the winter of the temperate zone of the northern hemisphere, or of the months December–February. The sentence quoted above may be a little surprising for the first moment, but certainly no more so, and no more absurd than expressions such as: 'At the Cape of Good Hope January is the hottest month', or 'In the temperate regions of the southern hemisphere summer comprises the months December to February'. Certainly nobody would object to statements of this kind, and it seems, therefore, that a mental abstraction which is easy enough in some cases is considerably more difficult in other cases, though I cannot well see why this should be so. There were no such difficulties for the first European settlers in the tropics and in the southern hemisphere. They called the hot or dry season 'summer' and the cold or wet season 'winter' without any regard to the seasons at home, and in many instances even without regard to the temperature at the place where they were living: in several regions of tropical America the year is divided into the four seasons of *verano* ('summer': long dry season), *invierno* ('winter': long wet season), *veranillo* ('little summer': short dry season), and *invernillo* ('little winter': short wet season), in spite of the fact that the temperature is highest during the rains, thus during the local 'winter'.

Any difficulty in the denomination of the seasons can be overcome by simply putting 'northern' (or 'north') and 'southern' (or 'south'), respectively, before the ordinary names of seasons every time when a misunderstanding may be anticipated. This is much simpler than burdening the language by a number of new scientific terms and will be understood also by persons who have no knowledge of Greek. It also does not seem very practical to use, like Dr. Baker, the astronomical seasons: for meteorological and biological purposes as well as in everyday life, the meteorological seasons are to be preferred. We have thus: northern winter or southern summer: December–February; northern spring or southern autumn: March–May; northern summer or southern winter: June–August; northern autumn or southern spring: September–November.

A few examples may be given. If a man living in Europe says that he was in London last summer, or a man living in South Africa says that he was in Cape Town last summer, this is quite clear, and there is no need of adding 'northern' or 'southern'. If a man living in Europe says that he spent last summer in Cape Town, this might cause misunderstandings, and it would be advisable to state whether the northern or southern summer is spoken of. There is no possibility of misunderstandings in statements like the following ones: 'I spent the summer of 1937 in London', or 'I spent the summer of 1936–37 in Cape Town', or 'In south-western Ceylon the north winter is the hottest season', or 'The migratory bird *X* spends the northern summer in Europe and the northern winter in South Africa', or 'The bird *Y* breeds in England as well as in New Zealand during the (local) summer months', or 'The bird *Z* breeds in England as well as in New Zealand during the northern spring', or 'In certain regions of tropical America the northern summer is the wettest and hottest season, though locally called winter'.

Codeine in Indian Opium

AN anomaly has crept into my article on "Chemistry of Indian Opium" published in NATURE of July 17, 1937 (140, 92–93).

On p. 92 (col. 1), the figure for the codeine content of Indian opium is correctly given as 1–2 per cent. On the same page (col. 2), at the end of the first paragraph, the codeine content of opium is shown as 2–4 per cent. This latter figure was taken from a departmental report rather difficult of access, and is the figure given by Prof. Dunston. The reference was given in the original article, but was unfortunately eliminated in the process of compression.

In his "A.B.C. of Narcotic Drugs", O. Anselmino also gives this figure for codeine in opium in the words: "Said to be 2 to 4% at Jeypore". It is not stated upon what analytical basis these figures are quoted, but it should be made clear that the usual codeine content of Indian Excise opium is between 1 and 2 per cent.

Points from Foregoing Letters

FURTHER evidence for nuclear transformation by the capture of a K-electron from the extra-nuclear structure is provided by Wilson-cloud photographs, submitted by Dr. E. J. Williams and E. Pickup, of the photo-electrons produced by the K-characteristic radiation, the emission of which follows the removal of the K-electron. The striking feature is that, for the active nucleus concerned in these experiments, the capture of a K-electron appears to be at least 1000 times more probable than the emission of a positive electron, a process which would lead to the same final nucleus.

Auroral spectra obtained by Prof. L. Vegard show that the relative intensity of the red line 6300 A. increases in passing to the upper part of the aurora (type A), while the relative intensity of the green line 5577 is greater in the lower auroral region. Prof. Vegard suggests that the enhancement of the red at the higher altitude may be due to oxygen atoms excited to the $^1D_2$ state through collisions between metastable nitrogen molecules and ozone molecules, produced by the short-wave radiation from the sun. Type B of red auroras have a red colour along the lower border due to an increase in the intensity of the first positive group of red lines, in the infrequent cases when the aurora reaches very low altitude.

In connexion with the hypothesis concerning the origin of the zodiacal light, Sir Joseph Larmor directs attention to an error for which he was responsible in reprinting Poynting's Collected Papers, which resulted in doubling the value of the suction of fine orbital dust into the sun. Sir Joseph envisages a nebula-like thick disk around the sun, remains of the original whirling solar nebula, still existing beyond the earth's orbit. This nebula may be considered of the type of the rings of Saturn, only enormously less closely packed. Its particles, as shown by the fact that the zodiacal light shows no scattering effect, must be larger than the wave-length of light.

Dr. A. Mercier states that if one tries to define a model of the primitive earth as a polytropic gas sphere, the conditions in its interior are found to be such that metallic vapours, particularly iron, must condense in a thick outer layer, from which the iron core usually postulated is produced.

Lieut.-Colonel L. M. Davies reports the discovery by A. G. Davis, recently confirmed by himself, of characteristic Upper Ranikot (Palæocene) fossils in beds on the western frontier of Persia. This is much the most western location of true Ranikot beds yet to have been recorded.

Further evidence concerning the probable structure of corticosterone (an active crystalline compound from the adrenal gland) is reported by M. Steiger and Prof. T. Reichstein, who find that corticosterone can be chemically transformed into the hydrocarbon allopregnane. The presence of a steroid structure is supported by the new data.

By adding ascorbic acid to the blood plasma, plus sodium oxalate, of a fowl affected by erythroblastosis (a disease characterized by the presence in the bone marrow of large numbers of colourless nucleated cells thought to be rudimentary red blood corpuscles) Dr. E. Morelli and Dr. A. Vercellone find that an inactive material is precipitated while the clear fluid becomes more active than before in producing the disease in other fowl. This result differs from that obtained by Claude and co-workers; in a somewhat analogous case, they found that the activity of the plasma in the case of fowls suffering from Rous sarcoma, the active principle was carried down by the precipitate upon acidifying the liquid.

By germinating Bengal gram in distilled water and in solutions with manganese equivalents of 1 in 10^6, 1 in 10^5 and 1 in 10^4, M. N. Rudra finds that the amounts of ascorbic acid synthesized in the latter solutions are higher than those produced in distilled water.

An experiment indicating that the carotene and xanthophyll in cooked spinach and carrots is almost entirely excreted in the fæces, is described by M. van Eekelen and W. Pannevis. Better assimilation takes place when the carotene and xanthophyll are dissolved in oil.

The study by K. C. Misra of the floral anatomy of *Wormia triquetra*, *W. Burbidgei* and *Dillenia indica*, three members of the Dilleniaceæ, has brought to light two very unusual features. First, the flower stalk contains several conducting strands, and secondly, the ovular trace branches repeatedly within the ovule.

Boris Ephrussi, Yvonne Khouvine and Simon Chevais find that *Calliphora* extracts considerably increase the number of facets in the eye of the Bar mutant of *Drosophila melanogaster*. They think that the extract contains a morphogenetic (facet-forming) substance under genetic control.

From tests on Armco iron wire, Dr. T. F. Wall infers that there is one diameter for which the permeability of the wire is a maximum and that the permeability rapidly falls off as the diameter is increased or decreased from this critical value; also that there is a surface layer of the wire which is magnetically harder than the core; and that by coating the wire with suitable material followed by heat treatment, the magnetic quality may be controlled over a wide range.

Research Items

Microliths from the Central Provinces, India

THE excavation of a rock-shelter, Dorothy Deep Shelter No. 1, west-north-west of Pachmari in the Mahadeo Hills, Central Provinces, India, by Dr. G. R. Hunter has brought to light an extensive series of microlithic quartz implements. An important feature is that the finds are stratified. In interim and final reports (*Nagpur Univ. J.*, 1, 1935; 2, 1936), the excavation of the shelter, which began in 1932 and was continued in 1934 and 1935, is described in detail. Two periods of occupation were distinguished: one of a later people using pottery, and an earlier civilization with quartz implements of characteristic Tardenoisian geometric form, without pottery or any trace of metal. The two strata of occupation were not separated by a sterile layer. This might have been expected from the fact that the character of the shelter was not such as would lead to the accumulation of deposits, except as the result of occupation. There is, in fact, an overlap of the two stratifications owing to the disturbance of the surface of the lower level during the later occupation. A human skeleton was found in the lower deposits, which was evidently not a burial by the later inhabitants. Unfortunately the remains were not sufficiently well preserved to admit of any conclusions as to the racial characters of the early inhabitants. As the find of worked or partially worked implements is roughly proportionate to the number of flakes, it seems probable that the shelter was a mesolithic factory. Quartz pebbles are abundant in the neighbourhood. The greatest depth at which pottery belonging to the later culture was found was twenty inches. No evidence was found of habitation earlier than mesolithic. As regards the evidence of stratification, there appears to be a true sequence of development in the microliths, but this still has to be worked out in detail. It should provide important evidence for the chronology of Indian microliths and possibly for those of other parts of the world.

Holy Days among Serbian Gypsies

DR. ALEXANDER PETROVIĆ continues his investigations among the Serbian gypsies with an examination (*J. Gypsy Lore Soc.*, Ser. 3, 17, 1) of the institution of the Slava, which they have adopted from the Serbs, but with modifications due to their own ideas and needs, as well as to misunderstanding of the true character of this institution. The Slava is a custom essentially Serbian, and found among no other Slavic nation. It is supposed that when the Serbs adopted the Christian religion, each individual or group chose a Christian saint to act as the protector of the house and family, and to fill the void created by abandoning the family or tribal spirit associated with ancestor worship. To the Slava saint, his domestic protector, the Serb appeals when he fears calamity; and the Slava is celebrated as the feast of this patron saint. Some Serbian families celebrate a 'Preslava' during the summer. Both Slavas are inherited in the male line. The Slava is celebrated solemnly and as richly as possible, a great number of guests being invited. The gypsies, while adopting the Slava, failed to understand the difference between it and the holy days of the Church, and came to the conclusion that every Christian feast, including Christmas, Easter, etc., might be turned into a Slava. Some recognize a slight difference, making a 'kola' (a wheat flour cake) which is carried into the church on holy days. Others make a kola on all occasions. Generally the gypsy adopts a new Slava only in case of some misfortune, usually illness, when the new saint, to whom an obligation is incurred, is chosen by means of a ceremony in which the patient chooses one of three candles each dedicated to a saint. He prays to the chosen saint, and if he recovers, honours him with a Slava, which may be kept throughout the remainder of the patient's life. This Slava is not observed after his death by his children, except possibly by the offer of a candle. An individual may observe more than one Slava and in one instance the devotee observes five.

North American Collembola

BULLETIN 168 of the United States National Museum (1937) consists of a monograph on North American Collembola of the family Isotomidæ, by the late Dr. J. W. Folsom. All the known nearctic species of Isotomidæ have been considered in this monograph, and of the 66 species and 16 varieties dealt with, 28 species and 2 varieties are described as new. Not only has the author examined all the type specimens of the species of Isotomidæ described from North America, but he has also compared most of these with palæarctic specimens. Of the nearctic forms, 21 species and 9 varieties are found to be also palæarctic in distribution. Isotomidæ are generally regarded as having originated from forms resembling *Achorutes*, and in the species of *Guthriella* (described in this work) a better link has been found, between the Isotomidæ and Achorutidæ, than was hitherto known. Dr. Folsom's monograph, which is illustrated by 460 figures, is one of the most exhaustive studies of any group of Collembola yet published.

Decapod Larvæ from Madras

MR. M. KRISHNA MENON describes a number of planktonic larvæ in his recent paper "Decapod Larvæ from the Madras Plankton" (*Bull.* Madras Government Museum. New Series. Natural History Section, 3, No. 5, 1937). As he obtained several post-larval stages from the later larval stages, certain of his species are identifiable; in other cases he only gives the genus and even this is often queried, although good series of larvæ were available and their characters noted in great detail. As so little is known of the life-histories of Indian decapods, these notes are valuable and contain much that is new. Specially interesting is the fact that the author finds 12 pairs of gills in the fourth larval stage of *Albunea symnista* and 13 in the fifth larval stage, the adult only having 10 pairs. The megalopa of *Ethusa investigatoris* from the last larva resembles the adult very closely, and it was found that even at this early stage it covers its body with anything that is handy. It is hoped that Mr. Menon will continue these studies of the life-histories of Indian decapods, which are for the most part practically unknown.

Antarctic Crinoids

THREE species of crinoids are described by D. Dilwyn John, all obtained at four points not far removed from one another to the west of Graham Land (Expédition antarctique Belge. Résultats du Voyage de la Belgica en 1897–99. Rapports Scientifiques publiés au frais du Gouvernment belge, sous la direction de la Commission de la Belgica. Zoology. Crinoidea. 1937). The collection, as the author points out, is of historical interest as being the first from the south of the Antarctic Circle and near the coasts of the continent, and it is important in including the only known specimens of the stalked crinoid *Ptilocrinus antarcticus* (here redescribed). The two other crinoids collected are the common Antarctic species *Promachocrinus kerguelensis* and *Anthometra adriani*. More than a hundred specimens of the former have been taken in the recent "Discovery" Investigations in the Falkland Section of the Antarctic, from the south of which the present material comes. Notes on these are shortly to be published in the Discovery Reports confirming A. H. Clark's opinion that *Promachocrinus vanhöffeni* and *P. joubini* are synonyms of *P. kerguelensis*, which is found to vary widely.

Mycologically Produced Chemicals

AN interesting paper by Mr. R. P. Cook on "Moulds and the Chemical Industry" appears in the *Scientific Worker* of November (9, No. 8, pp. 203–206). It describes the production of citric acid by fermentation of sugar in shallow receptacles. A felt of *Aspergillus niger* is grown therein, and is potent to ferment four or five refills of sugary liquid run successively beneath it. Gluconic acid, ink and oxalic acid can be produced by similar means. Ink and oxalic acid are made by fermentation with species of *Aspergillus*, whilst gluconic acid requires the ministrations of a *Penicillium* mould. Alcohol may be formed from starch directly by many species of *Mucor* and *Aspergillus*, which first effect the hydrolysis of starch into sugar, and later its subsequent fermentation to alcohol. The paper is of wide general interest, but many of the processes described retain their detail within closely guarded commercial secrets.

Spiral Hyphæ of Dermatophyte Fungi

THE fungi which attack mammalian skin have provided many problems for the mycologist, and the intensive study which they have evoked helps to elucidate more general questions. Messrs. A. M. Davidson and P. H. Gregory have investigated the occurrence of spiral hyphæ in five species of the genus *Trichophyton* (*Trans. Brit. Mycol. Soc.*, 21, Pts. 1 and 2, 98, Oct. 1937). These structures are believed to be organs of attachment which play a part in the infection of animal hosts from saprophytic sources. They are sticky, and when they adhere to an object, can break away from the mycelium. A large amount of inoculum would thus be transferred to the new host.

Nyasa-Shire Rift Valley

THE rift zone fractures in eastern Africa have been regarded as of late Tertiary age although certain associated volcanic rocks in the Tanganyika area and the Lower Zambezi date from the Cretaceous period. The Nyasa-Shire rift, forming part of this rift zone, has been generally regarded as due to the uplift and fracturing of a Miocene peneplain, but recently discovered Cretaceous beds within the northern Nyasa rift introduce a new factor. In the *Geographical Journal* of January, Mr. F. Dixey discusses the history of the Nyasa-Shire rift in the light of the evidence now available, including the relict uplands such as Nyika, Vipya and Zomba of 6,000–7,000 feet which surmount the Miocene peneplain. These are remnants of a great late Jurassic or early Cretaceous peneplain, or even of greater antiquity. Mr. Dixey contends that the instability which gave rise to the Nyasa-Shire rift and probably the Rukwa and Tanganyika rifts can be traced back to the early Cretaceous period with renewed movement in late Tertiary and post-Tertiary times.

Meteorological Depressions

GEOPHYSICAL MEMOIR No. 72 of the Meteorological Office, Air Ministry, is a discussion by A. H. R. Goldie of the structure of certain depressions that have passed across or near the British Isles in recent years. As the title of the memoir, "Kinematical Features of Depressions", suggests, it is a study primarily of the nature of the air motion in these depressions, and has been carried out in order to discover the type of vortex to which such storms approximate, with the view of arriving at an explanation of their development and life-histories. The greatest difficulty in studies of this kind is to derive from available wind data a general picture of the air movement such as could be obtained from a close network of well-exposed anemographs and pilot balloon stations, were such available. The author does his best to surmount this difficulty, with some measure of success as regards surface movement. He finds that except in an area around the barometric minimum, the average surface air movement is in accordance with that of a simple vortex (speed varying inversely as the distance from the centre); that in the part of the central area occupied by polar air the wind is sometimes proportional to distance from the centre, with some evidence that this area becomes larger with increasing age of the depression. Detailed analysis of this area showed a cell-like structure with convergence of both cold and warm air below 2 km. towards the main front through the centre of the depression, and upward motion above. The conclusion is reached that the energy for a depression is derived mainly from the high speed of the tropical winds, particularly in the higher levels, that is, from the planetary circulation, and that the vortex is started by the warming and humidifying of the polar air near a warm front. The results support modern Norwegian theory in a general way, although the typical structure of depressions seems to be arrived at through the circular and converging movement which is impressed upon the edges of the polar air mass.

Black Phosphorus

IT is nearly twenty-five years since Bridgman showed that white phosphorus was irreversibly transformed to a black modification at pressures of the order of 12,000 atmospheres and temperatures of about 200° C. He noted that for the first ten to fifteen minutes the transformation proceeded very slowly, and afterwards took place with almost explosive characteristics. A reinvestigation of this transformation in the same laboratory by R. B. Jacobs has just been published (*J. Chem. Phys.*, 5, 945; 1937). White phosphorus has been heated at approximately 13,000 atmospheres to about 205° C. for six different periods, all less than fifteen minutes and varying from each other by two-minute intervals. Then the pressure was reduced to half its highest value in order to retain the phosphorus in the solid state, and, on washing with carbon disulphide, a carbon-like powder was obtained in amounts bearing a close correlation to the times of heating. Visually this powder differed from the usual black phosphorus. Its density was 2·25 compared with 2·69. Whereas the usual black phosphorus gives distinct X-ray diffraction lines corresponding with an orthorhombic type of crystal structure, the 'new' black phosphorus gave no diffraction lines, and therefore it is either amorphous or microcrystalline. Measurements of the differences in the total heats between the various forms of phosphorus were obtained from the heats of reaction of the different modifications with bromine. These data indicated that the new black phosphorus is amorphous and a separate polymorphic modification. It has also been shown that the stable form of phosphorus below 560° C. is the crystalline black modification, and data illustrating the progression of stability of the different forms of phosphorus are given. Prolonged heating of amorphous black phosphorus at about 125° C. yields a brilliant violet modification of red phosphorus.

Examination of Colliery Ropes

FOR a number of years, the Wire Ropes Research Committee of the Safety in Mines Research Board has been conducting investigations into the deterioration and failure of colliery winding and haulage ropes, and has, from time to time, published accounts of these investigations. Colliery ropes are highly stressed and relatively complicated pieces of machinery liable to accidental damage and gradual deterioration which may gravely affect their strength, and the consequences of a failure, when men's lives depend on them, may be most serious. The law requires that each rope must be subject to two distinct forms of examination—a daily examination to ensure that it remains intact and is free from gross faults—a special examination carried out at least once every month when the condition of the rope is closely inspected and the progress of any deterioration is particularly noted. The former provides for cursory examination of the whole rope; the latter provides for detailed inspection at a number of places spaced out along its length. Out of 57 winding ropes which broke in service as a result of gradual deterioration it is stated that only 11 had been reported as showing signs of weakening. On investigation, the remaining 46 were found to exhibit such signs of deterioration as should have been noted by a vigilant examiner. For the information and use of those persons who are directly responsible for the examination of ropes, the Board has now issued a booklet entitled "The Examination of Colliery Ropes in Service" (London: H.M.S.O). It can be conveniently carried in the pocket, and sets out briefly the types of deterioration met with due to wear of different kinds, fatigue and corrosion, explaining their causes and how they may be recognized. The parts of the rope which should be examined with particular care, the methods of measurement and of examination and the limits of deterioration allowable are all set out clearly and concisely.

Refractive Powers

DURING the last thirty or forty years, the older definitions of the refractive power of a transparent substance, $\frac{\mu - 1}{\rho}$ of Gladstone and Dale, and $\frac{\mu^2 - 1}{\rho}$ of Newton, Selmeyer and Drude have been replaced by the $\frac{\mu^2 - 1}{\mu^2 + 2} \cdot \frac{1}{\rho}$ of Lorentz and Lorenz, where in each case μ is the refractive index for a definite wave-length and ρ the density. In the November and December issues of the *Journal of the Franklin Institute*, S. S. Kurtz and A. L. Ward make use of the available data for the refractive indices, dielectric constants and densities of liquid hydrocarbons over ranges of temperature often exceeding 100° C. and of pressure up to 12,000 atmospheres to test the relative values of the three definitions with regard both to light and to electricity, where the dielectric constant k replaces μ^2. Their conclusion is that the Lorentz-Lorenz expression should not be used except for rough approximations, that the Newton-Selmeyer-Drude should be used for the correlation of dispersion data for hydrocarbons, and that the form $\frac{\mu^2 - 1}{\mu^2 + 0 \cdot 4} \cdot \frac{1}{\rho}$ suggested by Eykman in 1919 should be used for the effects of temperature and pressure on both the refractive index and the dielectric constant.

Objective Prism Observations of Nova Lacertæ (1936)

D. T. Edwards and D. R. Barber have recently issued a paper with this title (*Mon. Not. Roy. Astro. Soc.*, 98, 1, Nov. 1937), in which they give an account of the spectrum of this nova up to September 3, 1936. The instrument used at the Norman Lockyer Observatory was the 12-in. McClean telescope with a 20° prism, and the plates were Barnet "Super Press". The first photograph showed the typical α Cygni absorption spectrum, and this was followed by different stages of mixed absorption and emission, ending with the purely emission spectrum of nebular type. Three tables are given in which are indicated the more prominent absorption and emission lines, in addition to notes regarding their characteristics, widths and dates of appearance. Other tables show absorption-line and emission-line velocities. In the case of the latter, there is a systematic progression of velocity from positive to negative values, both for *H* and metallic lines, and this presents some puzzling features. It is suggested that the effect may be caused by masking of the red edges of the bands by absorption, or unmasking of the violet edges, and may not be a velocity effect. There is no doubt, however, about the progressive changes of the apparent displacement, and independent work by Bobrovnikov has recently confirmed these.

Isotopic Composition of Ordinary and Uranium-Lead

IN the paragraph appearing in NATURE of January 1 (p. 43) under the above heading, data reported as having been found for uranium-lead actually referred to ordinary lead, and vice versa. Thus, ordinary lead chloride was found to have the isotopic composition ^{204}Pb, $1 \cdot 1_5$, ^{206}Pb, $24 \cdot 5_5$, ^{207}Pb, $21 \cdot 3_5$, and ^{208}Pb, $52 \cdot 9_5$ per cent, giving 207·21 for the atomic weight of ordinary lead, in exact agreement with the value given in the International Table for 1937. Uranium-lead from Katanga curite was found to have the isotopic composition ^{206}Pb, 95·1, ^{207}Pb, 4·9 per cent, giving an atomic weight of 206·01 (O = 16).

Industrial Organic Chemistry

New Dyestuffs Laboratories of I.C.I., Ltd.

THE unprecedented character of the Dyestuffs (Import Regulation) Act of 1920 was both an expression by Parliament of its conviction that an active and flourishing dyestuffs industry is essential to the life of Great Britain, and a recognition of the technical difficulties of developing such an industry in face of the priceless experience and established position of foreign manufacturers. An exhaustive review at the end of the period of ten years, for which the measure was originally enacted, resulted in 1934 in its being made permanent.

The largest of the interests thus sheltered is now known as the Dyestuffs Group of Messrs. Imperial Chemical Industries, Ltd., and the opening on January 11 of its new research laboratories at Blackley afforded a further opportunity of considering the results of the legislative venture of 1920. The event was thus one of most unusual interest and importance, and attracted a large gathering representative of academic, administrative and manufacturing interests. The impressions gathered can scarcely have been other than of deep satisfaction.

Apart from all that has been done by the Dyestuffs Group in developing the manufacture of products already known, the early discoveries of the ionamine and duranol series of dyestuffs for acetate silk have latterly been supplemented by the solacet and phthalocyanine series. Further, much progress has been made in the direction of that broadening of activity into other closely allied branches of applied organic chemistry which marked the growth of the Continental industry. This must be regarded as a normal and essential feature of healthy development, and one which will confer on the industry as a whole increased stability. Indeed, it is this expansion to include, for example, modern detergents and textile assistants generally, plastics and rubber, medicinal chemicals, insecticides and fungicides, which has led to the provision of the new laboratories. The close interrelationships of these various fields of work were illustrated in the laboratories by an extremely well-organized series of exhibits representative of "Chapters in the Development of Industrial Organic Chemistry", and described in a well-illustrated presentation volume bearing that title, as well as by demonstrations to conducted parties of visitors.

Prior to this, in a happily informal speech which prefaced his performance of the opening ceremony, Mr. John Rogers had indicated the general outlook of the Dyestuffs Group and discussed the conditions which make for success in the type of research for which the new laboratories are designed. His faith in the productivity of abstract research work and the following up of unexpected results, his plea for a long-term policy and his appreciation of the co-operation both with users of his Company's products and with academic institutions, must all meet with the most cordial approval. It cannot be doubted that adherence to this attitude will provide a sure foundation for the future success and prosperity of the Dyestuffs Group and at the same time a most potent stimulus to the development of organic chemistry in Great Britain.

The laboratories have been designed by Mr. Serge Chermayeff and are intended to be only the first instalment of a larger programme. They take up the main block of a three-storey building, 400 ft. long, running north and south, and are entered from a corridor on each floor extending along the whole of the west side. Twenty-one separate laboratories of uniform type are thus provided, each with a partial subdivision, by shelving, into units which accommodate one chemist and offer him a measure of privacy. Fume cupboards glazed on both sides and provided with electrical, gas, steam, compressed air, vacuum, and water services back on to the corridors, where removable panels allow easy access to the service pipes. Continuous windows along the east and west sides of the building give a maximum of continual daylight in the laboratories with protection from too great heat of the sun. Ventilation is entirely by conditioned air, separate ducts, of course, being provided to carry away gases from the fume cupboards. The flooring of cork tile eliminates noise from the laboratories, whilst an air of cheerfulness is contributed by the use of different colours against a background of white.

It will thus be seen that to a thoroughly well-informed and progressive outlook there have now been added amenities which are first-rate from both the æsthetic and the immediately practical points of view. We tender to Messrs. Imperial Chemical Industries, Ltd., our sincere congratulations on these most favourable auspices and at the same time our best wishes for the future success of their enterprise.

J. K.

Wool Industries Research Association

THE Wool Industries Research Association's previous report, reviewed in NATURE of January 16, 1937, was an innovation issued for the information of the general public and firms outside the Association, in view of efforts then being made to secure a statutory levy. It is now reported that insufficient additional support has been forthcoming to warrant the introduction of an enabling Bill into Parliament, and this scheme has been dropped for the time being. It is, however, emphasized that nothing has been left undone to urge the claims of research, and the need for its financial support on a scale more adequate to the magnitude of the industry's interests. Meanwhile, generous response has been made by a number of individual firms for the purpose of meeting a serious and unexpected deficit in revenue, and the

Council has decided upon a substantial increase in the rate of subscription for the processing sections of the industry.

The report refers to two circumstances which may delay the development by a research association of new processes—'teething' troubles accompanying their translation to commercial production, and requiring a willingness on the part of the industry to experiment, and the smaller incentive to bear the brunt of these troubles when results must be common property than when the knowledge gained is the exclusive property of a private firm.

Comment is again mainly devoted to the development of the processes, referred to in last year's report, for rendering wool 'unshrinkable' and for producing a permanent bleach.

The loss of 'handle' on chlorination is largely restored by 'fixanol'—this suggestion emanated from the Textile Chemistry Research Department of the University of Leeds—and it is now reported that substances of this type, which unite with wool substance, form a chemical link between the fibre and rubber latex, and a patented process has been evolved for rubberizing yarns to give water-repellent, moth-proof, and wear-resistant properties, and make available low-twist yarns of good strength.

Stress is laid on the importance of accurate measurement of fibre diameter as a fundamental necessity "for any progress to be made in the understanding of the manufacturing performance of wool", and "for the farmer to have reliable numerical data on which to base his breeding policy".

It is maintained that the fear expressed in some quarters that measurement of fineness in wool tops may become a bugbear in commercial dealings, could only be realized if it were used as a measure of quality, with the rather ambiguous comment that the latter is "a development which it is within the hands of the Trade alone to prevent".

Statistical analysis has also been applied to the variability of woollen card slubbing with the view of reducing uneconomic margins of tolerance.

Other subjects referred to as having received attention are the examination of proposed alternatives to olive oil for combing, of new detergents for wool scouring, and of the effect of various dyeing processes on the spinning power and handle of wool. An increased demand on the part of members for the investigation of special problems is also reported.

Thus it is evident that the Association is energetically pursuing investigations on the technical and statistical sides, which may disarm any criticism of the restricted output of publications in scientific journals. Readers appreciating the functions of organized research in industry will, perhaps, feel more confident than the Director of Research that the non-participating section will diminish, but this will follow less from the reproof he administers than from a conviction borne of a fuller demonstration that it is missing benefits by standing aside.

Rothamsted Experimental Station

THE form of the Rothamsted Report* for 1936 differs from those of former years in that a number of investigations which have extended over a period of years have been selected for detailed discussion, thus summarizing the results up to date. This type of annual report has an undoubted advantage in presenting the results of agricultural research, where a number of variable factors, such as seasonal effect, enter, tending to give uneven progress towards final conclusions; the results of one year may not give a representative picture of the work in hand. Though the work at Rothamsted is mostly of a fundamental type, the practical needs of the farming industry are kept continually in mind, the research programme being under constant scrutiny so as to follow up immediately those results likely to have a practical bearing. With long-period research, such as that embracing some of the field experiments which have been in progress for half a century, the need for such a policy is apparent, and it probably explains much of Rothamsted's secret of interesting both the research worker and the farmer.

The results of the various investigations on grassland problems come at a time when pasture management is a subject of topical interest and, for that reason, occupy most of this note; it may be mentioned that the recent International Grassland Congress visited Rothamsted in order to examine the Park grass plots. The Land Fertility Scheme, again, lends interest to the trials on the effects of manures on the botanical composition and yield of pastures. Attention is directed to the difficulties of drawing correct conclusions on the variations in the proportions of individual species as the result of manuring, because a decrease in one species may not, for example, be due to the direct action of the fertilizer, but to its being suppressed by an increase in another. Thus, the well-known effect of sulphate of ammonia in causing a decrease in the proportion of legumes in a mixed sward that is not closely grazed is due to their suppression by the greater growth of grasses resulting from this manure. It is interesting to note that the effect of lime has been most marked on the liberally manured plots, the plots standing out even in winter. Again, liming helped the sward to stand extremes of climate, heavy frost and drought having killed the herbage on the unlimed plots treated with sulphate of ammonia and mineral manures, while the grass on the limed plots was not affected. In the experiments with phosphatic manures, it has been observed that, by analysing the herbage and getting the figures for the percentage recovery of added phosphate, it has become much easier to interpret the results of the trials than by merely observing yields of hay. This is the sort of information that should be kept in mind when the time arrives for assessing the success or otherwise of the Land Fertility Scheme.

The effect of the composition of the original seeds mixture sown when laying down a field to grass has been studied in a ley put down eight years previously. Research of this type has established the fact that, under most conditions, there is no particular advantage in sowing a large number of species, since, in a few years, these become reduced to a few, such as perennial ryegrass, wild white clover, etc.; exceptions to this sometimes come to light, such as when Percival observed that, in the Thames Valley, all the species of plants sown were still found after nineteen years. In the ley studied at Rothamsted, the ryegrass, cocksfoot, timothy, rough-stalked meadow grass and wild white clover formed the overwhelming bulk of the herbage after eight years. It is interesting to contrast some features of these results with those found by Alun Roberts at a number of centres in Wales, where the rainfall is higher, and where there is hard winter grazing by sheep. At Rothamsted, cocksfoot, and particularly timothy, survived much better than at the Welsh centres. Again, in the west, Italian ryegrass had completely disappeared at every centre in three years, while at Rothamsted this variety proved unexpectedly persistent, contributing largely after eight years; it must be assumed that this persistence was due to self-seeding. The Rothamsted experiments are important for large tracts in the drier parts of England, where economic conditions have forced many to put down land to grass.

---

* Rothamsted Experimental Station; Lawes Agricultural Trust. Report for 1936. Pp. 294. (Harpenden: Rothamsted Experimental Station, 1937.) 2*s*. 6*d*.

The experiments on the composition of ryegrass are of particular interest in view of the position regarding the various methods of grass conservation. The high proportion of fructosan, which is soluble in cold water, found in spring grass when the panicle emerges, and the decrease in this substance on further maturity, indicates that research in this direction may throw important light on such questions as losses in conserving young and more mature grass by various methods, and the relative values at different times of the year of pasture grass having similar chemical composition when expressed by the conventional method.

Experiments on the relation of cultivation to crop yield have been in progress since 1926, these being concerned with a study of the effects of the standard operations, and with a comparison of standard methods with rotary cultivation. There is a considerable body of evidence from other countries that yields are not increased either by extra or deeper cultivation above a certain minimum well below what British farmers would accept, and eleven years experiments on heavy soil at Rothamsted and on light soil at Woburn tend to confirm this. Rotary cultivation, which produces a tilth in one operation, has given no harmful results when carried out on the same land year after year, provided that—for certain crops—it is done sufficiently deeply.

Other sections of the report, such as those dealing with the work of the Fermentation Department and of the Departments of Fungicides and Insecticides, and also of Entomology, are equally important because of the amount of valuable information contained in them.

Display and Reference Exhibits in Museums

By Samuel G. Gordon, Department of Mineralogy, Academy of Natural Sciences of Philadelphia

THE new mineral gallery of the Academy of Natural Sciences of Philadelphia contains seven sections devoted to educational exhibits, the William S. Vaux Collection, Pennsylvania minerals, the fluorescent minerals, meteorites, gem stones, and special exhibits (radioactivity, new accessions, loan collections, etc.)

Frameless cases, virtually glass envelopes (described in the *Museums Journal*, November 1936) were designed in which the plate-glass is supported by a minimum of metal. Such construction was found possible in large wall cases, table cases, floor cases and pedestals, with the result that visitors are less 'case-conscious'. The educational exhibits (What is Geology? What is a Mineral? What is a Crystal? The Interior of the Earth, etc.) are in wall cases lined with black suède-like paper which gives the incisiveness of a blackboard sketch. The labels, a tersely written *sequence*, are combined with the illustrative material (rigidly selected specimens, charts, maps, transparencies, models, instruments, etc.) in a *layout* in which lines, designs, colour, and other symbolic devices are used to develop a logical continuity. All other lines, arbitrary designs, meaningless colour, coarse textures, hardware, supporting accessories, ornamentation and distracting effects are avoided.

Less than 10 per cent of the minerals of the Academy collections are shown in the systematic series, about half in wall cases, and the rest in high table cases. Care was taken that each individual specimen, shown against black velveteen, was set up to the best advantage (four specimens took two hours apiece for this operation). Supporting means (mostly glass tripods) are unobtrusive. The green colour of glass shelves was found to be due to total reflection (within the plates) of the back edges; the colour was eliminated by painting the back edges black. Labels were printed on plastocele (cellulose acetate) with a lino-scribe, a device which uses printers' type and cuts. There is also an index with cross references to the minerals. Lighting (outside the cases) is concealed, and unobtrusive valances were used at strategic points in the wall cases to eliminate reflections.

The fluorescence exhibit (the first in America, following soon after that in the British Museum (Natural History)) is at the turning-point of the gallery. When reopened, it will be set in operation by the visitor passing a pair of photo-electric cells, and the automatic cycle (electric lights, ultra-violet lamps, darkness) will be synchronized with a four-minute record explanatory of the phenomena.

The focal point of the next section is another educational layout: "What are meteorites?" Elaborate series of cut gemstones, jades, birth-stones, ornamental stones are shown in the succeeding bay. The last section includes an exhibit of radioactivity, in which the story of its discovery precedes a demonstration using an ionization chamber connected with a circuit terminating in a neon lamp which flashes as gamma radiation enters the chamber.

Thus modern technical resources are being used to make exhibits educational and to stimulate interest in natural history. But what about the many specimens of which the rarity, obscure character, or specialized interest do not make it feasible to give them expensive display space ? How are these to be made available to the serious student ? What is to happen to the many specimens cluttering up museum cases when these are relegated to storage cabinets ?

It is probable that the answer will be found in the development of reference museums. We have all admired the efficient organization of libraries, where staffs have been trained in the cataloguing and care of books, and their preservation in fire-resisting structures. The huge bulk of accumulated natural history specimens in many of the older museums presents a storage problem. With the gradual extinction of many species of wild life, the growing scarcity of others, and the increasing difficulties of collecting, it is essential that what we already have be assured permanent preservation and greater accessibility to students.

Such collections could be compactly stored in metal cabinets in vermin-proof, fire-resisting library-stack-like structures. Specially trained curators could receive, prepare, catalogue, place and care for the specimens received by the museum. The distribution of specimens to research workers in their own and to other institutions, and of loan collections of duplicates to schools, would be in their hands. No small part of their activity would be to bring out of the stack, for examination at close hand, any specimen desired by a serious student.

An experiment in this direction will soon be made by the Mineralogical Department of the Academy. Visitors will be advised that any specimens they desire to see, if not on exhibition, will be placed by a member of the staff in a special, well-lighted case for their examination.

The German North Atlantic Expedition*

HAVING almost completed their examination of the data brought home from the South Atlantic Ocean by the *Meteor* in 1925–27, German oceanographers have set out to make a thorough investigation of the North Atlantic, and as the result of a conference between the Commander-in-Chief of the Navy, the council of the Deutschen Wissenschaft and the director of the Institut für Meereskunde, the German North Atlantic Expedition has been organized.

The plan of the new expedition is to complete the network of modern oceanographical observations over the Atlantic Ocean, linking up the work of the *Meteor* in the south with her subsequent investigations in Iceland and Greenland waters, and with the work of the American *Marion* and *Atlantis* expeditions in the Davis Strait and the western North Atlantic. The area to be covered extends from 15° N. to 64° N. between the west coast of Europe and Africa and a line from the West Indies to Nova Scotia.

The main objects are the study of the physico-chemical structure of the sea, and meteorology. It is hoped that a large number of scientific and practical problems, many of them connected with the Gulf Stream, will be solved, and Prof. A. Defant, who is directing the work, is confident that information likely to be of material assistance in long-range weather forecasting will be obtained.

The *Meteor*, now re-engined as a motor-vessel with a cruising radius of 9,000 miles at an average speed of 12 knots, is to be used, and the Institut für Meereskunde, the Deutsche Seewarte, the Marine Observatories of Wilhelmshaven and Kiel, and the State Meteorological Department, are co-operating with the Navy. The whole project is not to be accomplished in one commission, but by a number of shorter voyages.

The first voyage, partly a trial cruise, and mainly an addition to the original programme, was started in February and completed in May of last year. The region from 10° N. to 28° N. between the African coast and 30° W. was examined; about seventy stations were worked at 60-mile intervals on six east-to-west lines, half of them falling between the African coast and the Canary and Cape Verde Islands. At each of the inshore stations hourly observations were made over a period of 60 hours, and one series of current observations over a period of 48 hours was made with the ship anchored in deep water. Six oceanographers, two meteorologists and two magneticians were carried, and the officers and crew numbered 121.

Only a very preliminary account of the results is available, but it is clear that much important information has been gained. The whole of the coastline of this part of Africa is marked by upwelling, and although the water comes to the surface from relatively shallow depths, the surface temperatures may be 5° or 6° C. colder than those farther offshore. The region also has a rich plankton population. The continuous hourly observations reveal changes of very short period, and show that the conditions in the thermocline at a depth of 25–60 metres respond very quickly to changes at the surface. The chemical work included determinations of silica, phosphate and nitrite.

A large number of observations were made on the upper-air currents, 209 balloons being followed by the new radio-ranging method, which seems much better adapted for work in an unsteady ship than the usual theodolite method. The nautical staff carried out an extensive programme of echo-sounding, and made researches into the reliability of modern instruments and methods of fixing positions at sea. Magnetic observations were made in the Canary and Cape Verde Islands.

During the three and a half months voyage, much was accomplished, and it is evident that the investigation of the greater part of the North Atlantic Ocean by similar methods will produce most important results.

G. E. R. D.

Science News a Century Ago

Locomotives on the Liverpool and Manchester Railway

AT a meeting of the Institution of Civil Engineers on January 30, 1838, Edward Woods, the chief engineer of the Liverpool and Manchester Railway, read a paper containing an account of the alterations which had been found necessary in the first locomotives used on that line. These alterations, he said, consisted principally in strengthening every part of the engines, and the consequent increase in the weight was such that it became necessary to re-lay the whole of the line with stronger rails, and as a temporary provision to add a third pair of wheels behind the fire box. Woods then went on to refer to certain necessary conditions in the structure of locomotives, and the means adopted to obviate the rocking motion and the unsteadiness arising from lateral undulations. With respect to the objections urged against the use of six-wheeled carriages, he observed that the adhesion though less was sufficient, and that the additional weight did not exceed two hundredweight, or produce a diminution of traction amounting to more than one two-hundredth of the whole; and that the additional strain and friction on passing curves may be entirely obviated. He then discussed the distribution of the whole weight of the engines on the wheels, which weight on the average amounted to eleven and a half tons. Woods was twenty-four years of age when he read this paper. About fifty years later he served as president of the Institution.

Heat of the Earth

AT a meeting of the Geological Society on January 31, 1838, an extract from a letter addressed by Sir John Herschel to Lyell, dated Feldhausen, June 12, 1837, was read. It contained some additional observations relative to the writer's views respecting the increment of temperature which may be produced in some places within the crust of the earth, by the distribution of additional beds of sediment over the bottom of the ocean, and the consequent elevation of those tracts. In this letter, Sir John Herschel expressly alluded to Mr. Babbage's view on the subject given in a paper on the Temple of Serapis read in March 1834, but he stated that he was not aware of that gentleman having speculated on the same mutual reaction of the surface and the interior of the globe, until his attention was recently directed to the circumstance.

Ornithological Society

IN the report of the Council of the Ornithological Society read at a meeting held on February 2, 1838, it was stated that Mr. Blyth had been appointed assistant secretary and curator of the museum, the latter post being rendered necessary by the munificent loan of the Hon. W. T. Fiennes. It was announced that the collection of living birds had sustained little injury from the severity of the winter. Mr. Blyth then commenced a discourse on the geographical distribution of birds by enumerating first a variety of groups and species which are confined to particular regions; and secondly, others, and some of comparatively trivial value, which are diffused over the greater portion of the world. He illustrated the subject by adducing various phenomena of geology and botany; enumerated and explained some of the more interesting analogous adaptations of different types of form, geographically separated; surveyed theories of zoological provinces, particularly commenting on Dr. Richardson's, and directed particular attention to the fact that those North American birds which have no generic representative in Europe, and those European genera which have no species proper to America, are almost without exception, migratory.

Dr. Neil Arnott's Stoves

DR. NEIL ARNOTT, F.R.S., in 1838, published his work "On Warming and Ventilating: with Directions for Heating and Using the Thermometer Stove". The book was reviewed in the *Athenæum* of February 3, 1838. "Dr. Arnott", said the reviewer, "has already established his reputation as a practical benefactor to mankind, and now he has come before the public again with another application of philosophic principles to domestic use, which will add in no ordinary degree to the comforts of all, but most especially of the humbler classes. . . . The superiority of the apparatus consists in the power of so regulating the afflux of air to the fuel as to consume no more of the latter than is absolutely necessary to heat the apartment to the required degree. . . . During the winter Dr. Arnott kept his library at 60–63° F. with an expenditure of 6 lbs. of Welsh coal a day. . . . The stove is with us all important, and we have thought it our duty to bring it under the consideration of our readers. There is no mystery—no concealment in the matter. In this as in the water bed, Dr. Arnott has not even sought to derive pecuniary benefit from his labours and discoveries; instead of securing a fortune by patent privileges, he has with a noble liberality, worthy of national recognition, made the discovery public."

State of Medical Science in Spain

THE issue of the *Lancet* of February 3, 1838, contains a letter with this heading from William Lambton, late surgeon attached to the British Army Legion, illustrating the lack of respect shown to the medical profession in Spain in contrast with the high esteem in which it was held in France and England.

According to Lambton, when the British Legion went to Spain in 1835, it was notorious that the medical officers had the worst billets, and with but few exceptions received the most cavalier treatment from the Spaniards. "The surprise", continues Lambton, "which this want of respect created in my mind was entirely eradicated on perusal of the following advertisement, which appeared in a Madrid paper: 'Wanted a medical man who will undertake to attend a parish four leagues from Madrid: the salary is 4000 reals (about £40) a year, out of which he is to pay 375 reals for the maintenance of the poor. His keeping of a barber's shop, however, will prove no detriment to his capacity for the office, as it is understood that he will be allowed to make what he can by shaving. He must, however, be a chartered member of the Madrid faculty'. . . . Spanish surgeons", says Lambton, "are without exception the coolest operators I ever saw in my life, for when engaged in an operation in their own hospital they are generally to be seen with a pipe or cigar in their mouths, swearing at the cries of the patient or at any mishap which may occur during the operation. Nor are they by any means proud of their position, for they resign the knife to any professional bystander who is willing or anxious to operate."

University Events

CAMBRIDGE.—The Iron and Steel Industrial Research Council has approved of a grant being made by the Alloy Steels Research Committee (a Joint Committee of the Iron and Steel Institute and the British Iron and Steel Federation) at the rate of £500 a year from January 1 for research on corrosion fatigue under the direction of Dr. U. R. Evans. Although this grant is made for one year only, it is understood that there is every intention of renewing it for 1939. A former grant from the Iron and Steel Industrial Research Council in aid of Dr. Evans's research was made in 1936.

At Clare College, W. B. Reddaway, of King's College, has been elected into an official fellowship. He gained a first class in the Mathematics Tripos, Part 1, in 1932, and a first class in the Economics Tripos, Part 2, in 1934.

EDINBURGH.—At a graduation ceremony on December 17, the degree of D.Sc. was conferred on Kalipada Biswas, superintendent of the Royal Botanic Garden, Calcutta, for a thesis entitled "Studies on the Systematic Botany of India", and on Sanford Sterling Munro, for a thesis entitled "Studies on the Genetics and Physiology of Reproduction in the Fowl".

LEEDS.—Dr. Geoffrey Holmes has been appointed to a newly instituted honorary lectureship in medical hydrology.

Mr. Charles Ludwig has been appointed to a demonstratorship in physiology.

OXFORD.—The Herbert Spencer Lecture will be delivered on February 25, at 5 p.m., in the Examination Schools by Prof. Ernest Barker, Laura Spelman Rockefeller professor of political science in the University of Cambridge. The subject of Prof. Barker's lecture will be "Natural Law in the Political World".

D. KEILIN and E. F. HARTREE. Mechanism of the decomposition of hydrogen peroxide by catalase. A new explanation of the mechanism of the decomposition of H_2O_2 by catalase is proposed. According to this explanation the reaction is brought about by the successive reduction of the catalase iron by H_2O_2 and its reoxidation by molecular oxygen. This explanation is supported by experiments. The inhibitors of catalase can be separated into two groups, those like KCN, H_2S, C_2H_5OOH which inhibit the reduction of catalase iron by H_2O_2 and those like azide, hydroxylamine and hydrazine which inhibit the reoxidation of the reduced catalase by molecular oxygen (Keilin and Hartree, 1936). The decomposition of H_2O_2 by pure catalase preparations is not inhibited by CO in presence of even a very small concentration of oxygen, which shows that the reduced catalase has a much greater affinity for oxygen than for CO. Some catalase preparations have been obtained which show a more or less marked light-sensitive inhibition by CO. Pure catalase preparations become sensitive to CO in presence of a very small concentration of azide, cysteine or glutathione, substances which apparently inhibit the reoxidation of reduced catalase.

H. J. A. DARTNALL, C. F. GOODEVE and R. J. LYTHGOE: The effect of temperature on the photochemical bleaching of visual purple solutions. The theoretical considerations developed previously for the photochemical bleaching of a light-absorbing substance have been extended to include the case where the products absorb light. Twenty-five out of twenty-nine experiments with visual purple were found to be in accordance with the previous theory. In the remaining four, the decomposition of a coloured product, 'transient orange', proceeded at a rate comparable with the rate of bleaching of visual purple. The quantum efficiency of the bleaching process was found to be independent of temperature over the range 20° to 60° and of pH from 7 to 9·2. It is concluded that the quantum efficiency is equal to or not much less than unity, and that the molar extinction coefficient ($\lambda = 506\text{m}\mu$) is $1{\cdot}41 \times 10^4$.

J. W. HUGHES: The monaural threshold: effect of a subliminal contralateral stimulus. The change of threshold intensity in one ear when a note of fixed subliminal intensity is sounded in the other has been determined by direct experiment. The results of the investigation show that for two notes in unison, the total energy required in the two ears at the 'binaural threshold' is equal to the energy required in one ear at the monaural threshold, independently of the actual division of energy between the two ears.

Paris

Academy of Sciences, December 13 (*C.R.*, 205, 1189–1268).

MARIN MOLLIARD and ROBERT ECHEVIN: The secretion of the fly-catching Caryophyllaceæ. The Caryophyllaceæ present a series of secretions localized in the upper part of the plant, consisting essentially of a sugary material. The secretions vary slightly from one species to another.

DRAGOSLAV S. MITRINOVITCH: The differential equation of the geodesic lines of spiral surfaces.

GEORGES KUREPA: The hypothesis of the continuum and partially ordered ensembles.

STEFAN BERGMANN: A connexion between the theory of elliptical partial differentials and that of the functions of a complex variable.

CAIUS JACOB: The problem of Dirichlet in two dimensions.

JULIEN KRAVTCHENKO: The problems of conformal representation of Helmholtz: the study of a limiting case in the theory of the (ship's) wake in a perfect fluid.

LUCIEN HIBBERT: The surface of the moduli and automorphy of the polynomials and of integral functions.

J. KAMPÉ DE FÉRIET and A. MARTINOT-LAGARDE: The distribution between the mean motion and motion of agitation of the energy dissipated in the turbulent flow of an incompressible fluid.

ALEXANDRE FAVRE: Study of the Toussaint-Carafoli tunnel and of hydrodynamic movements in two dimensions.

HENRI MINEUR: The equilibrium of star clusters when the differential rotation is neglected.

HERVÉ FABRE: The absolute orbits of Gyldén.

TCHENG MAO-LIN: The spectrophotometric study of the minima of Algol. According to earlier work, the minimum of Algol is produced later for the blue rays than for the red. This is not confirmed by the author, who concludes from his observations that for all radiations in the interval 3900–6500 A. the minimum of Algol is produced at the same time within 1 or 2 minutes.

Constantin Salceanu : The measurement of the velocity of sound in liquids by a resonance method. A modification of Bungetzianu's method has been applied to measuring the velocity of sound in seventeen liquids and the results compared with those obtained by A. Cisman by a direct method.

Albert Zmaczynski and Albert Bonhoure : The boiling point of water as a function of the pressure. Owing to the discovery of an error in the temperature coefficient of the bridge resistances of the platinum thermometers used in earlier work, the formula given (*C.R.*, **189**, 1069) is now corrected.

Jacques Vorobeitchik : A new objective method of heterochrome photometry.

Maurice Parodi : Study of the transmission of blende and of some halogen derivatives of copper and of cadmium in the extreme infra-red.

Michael Duffieux and Jean Bollot : A method for the study of the hyperfine structure and the width of absorption lines.

Raymond Ricard, Marguerite Givord and Françoise George : The spark spectra of cæsium.

Jacques Solomon : The disintegrations produced by electrons of very great energy.

Pierre Jacquet : The electrolytic polishing of aluminium. The electrolytic method of polishing previously described can be applied with advantage to a soft metal such as aluminium.

G. Austerweil and A. Fiedler : The preparation of a purified water comparable with distilled water by the exchange of ions.

Mme. Raymonde Duval and Clément Duval : Differential electro-titration.

Paul Goissedet and Robert Despois : Some camphoric *N*-alkyldiamides.

Georges Zbyszewski : The discovery of new deposits of terrestrial vertebrates in the Neogene in the neighbourhood of Lisbon, Portugal.

Science in Administration

THE position and functions of the scientific or technical expert have been the subject of many discussions and much difference of opinion. The general view of administrators is that "The expert should be on tap but not on top" ; but this arises from a widespread official assumption that intimate knowledge of a particular subject—unless it is of a literary or historical character—is a disqualification for an administrative post. The point of view of the professional civil servant was stated in a leading article in the November issue of *State Service*. The article suggests that a remedy of current social and economic maladjustment can only be found in the intensive use of the methods of scientific research and inquiry in problems which have hitherto generally been regarded as outside their province. If the achievements of the chemist, the physicist, the biologist and the engineer are to be correlated with the processes of public administration, and not stultified or misapplied through the inability or reluctance of politicians and administrators to appreciate the significance of new scientific development, the expert's processes of thought and action must be extended into fields of human activity where they are at present rarely encountered.

These reasons themselves have led the Institution of Professional Civil Servants to maintain insistently that, in the interests of efficient government, the heads of professional, scientific or technical branches of the Civil Service should be given an unconditional right of access to Ministers in charge of their department on all matters in which their special knowledge provides them with a particular qualification to advise. The soundness of this contention is now scarcely challenged, however practice may depart from the principle. There is, however, another point of view, which was very ably advanced by Dr. G. W. C. Kaye in his address to Section A (Mathematical and Physical Sciences) at the British Association meeting at Nottingham. Dr. Kaye challenged the dictum that qualities of leadership are more likely to be developed by the old humanitarian studies than by the natural or mechanical sciences, and ridiculed the idea that technical or scientific workers invariably require to be mothered by full-blooded non-scientific or quasi-scientific administrators.

A scientific training may be the medium for the development of latent administrative ability as much as any other career and probably more than most. Restriction of the opportunity of scientific men who possess administrative ability to advance to the highest positions of administrative responsibility, whether in the State service, in industry or elsewhere, is not only unfair to the scientific worker as a class but is also a danger to the State, by limiting the resources upon which it can draw for a type that in any event is not easy to find. The significance of this point is well illustrated in Sir Josiah Stamp's recent address on the administrator and a planned society to the Institute of Public Administration, although he nowhere referred to it explicitly.

Sir Josiah sees the problem of administration as fundamentally that of securing a greater fitness to achieve approved ends, rather than obtaining any vision of a changing task which might be more than a question of degree and involve a different type of administrator. The responsibilities of the administrator are now so wide and numerous that the question arises whether a new kind of administrative technique and ability is required, whether different aptitudes and temperaments are logically involved, and whether the mental training should have some radical redirection.

This question of the type of administrator is all the more important in that the further question of the type of administration required in modern society has been raised in many quarters, for example, in the study of "British Experiments in Public Ownership and Control" by Mr. T. H. O'Brien, promoted by the Institute of Public Administration, or Sir Daniel Hall's discussion of possible modifications in the administration of democratic Governments to promote planning and efficiency, recently contributed to the *Nineteenth Century*. The two questions are interlocked, but we cannot be sure that we are getting the best out of the existing system unless we are using the best type of administrator in that system.

Equally, of course, it is true that an existing administrative system may be condemned as inadequate because by recruiting on too narrow a basis or through other deficits it fails to obtain or develop the best type of administrator. For this reason the recently published series of essays on "The British Civil Servant", some of which originally appeared in the *Political Quarterly*, are of special interest and significance, particularly the essay by Mr. F. A. A. Menzler on the expert in the Civil Service, and the discussions of the recruitment and training of officers in the Civil Service and the Local Government Service.

It is indeed strange that in the multitude of books on planning there is little reference to the administrative problem, and the fact that the new responsibilities involved in such corporate enterprises demand new qualities and new skills which may be the very antithesis of those required in the development of a successful one-man concern is largely ignored. As Dr. Robson suggests in reviewing a century of municipal progress, a more constructive type of administrator is required who sees possibilities and opportunities rather than difficulties and dangers, and who possesses creative ability and the capacity to promote energetic and far-reaching projects.

Under such conditions administrative ability is of greater rather than less importance, even if we are concerned with a slightly different type of administrator. Technical factors have to be assessed, but possibly technical factors in not one but half a dozen or more fields, and the administrator must consider the indirect as well as the direct effects of the proposed action or policy. The task of the administrator in the future is, in fact, as Sir Josiah Stamp points out, increasingly to secure the maximum net social product, and success of a measure or policy cannot be judged merely by sectional statistics but only by the effect on the national welfare when all repercussions have been taken into account.

This in itself clearly indicates the unsuitability for such responsibilities of the business man of the single management type, accustomed to fixing his own goal and achieving it in a competitive world, as well as the exactly trained civil servant accustomed to the analytical application of a legislative programme in a statute and working to the elaboration of a completely static programme. As a corollary it again emphasizes the importance of tapping all channels to secure an adequate supply of men of the requisite ability and vision.

If, however, it is essential that the highest administrative posts should be recruited from the widest possible field, technical and scientific as well as others, the question of training as well as of final selection remains. In this field, the idea of the staff college has only been tentatively explored, and the possibilities of vocational selection in regard to the higher posts as distinct from entrance to industry have scarcely been probed. Indeed, vocational guidance only becomes possible when the requirements for the post to be filled can be defined with some exactitude.

Obviously in this field such bodies as the National Institute of Industrial Psychology, the Institute of Industrial Administration, and the Institute of Public Administration have important contributions to make. What, however, in the first instance delays progress is the general failure, due to mis-education, to realize that scientific research and technical advance are producing strains and stresses in the structure of society which, if they do not receive prompt attention, may bring about the destruction of the social order. The status of the specialist in the Civil Service is merely symptomatic of society's general attitude towards those who are reshaping social environment.

The present unsatisfactory position has been pointed out authoritatively on repeated occasions in recent years. A report of the British Science Guild in 1931 strongly condemned the inefficiency of the practice of excluding officers of the expert class from the important administrative positions responsible for the direction of the work, and contrasted this position with the success of the opposite policy pursued in large-scale progressive industry. The report of the Royal Commission on the Civil Service, which appeared almost simultaneously, disappointed any hopes of this position being rectified at an early date, and instead betrayed a fundamental failure to appreciate the significance of the expert in public administration. In contrast with this, the Bridgeman Committee, reporting on the Post Office in 1932, was the first public inquiry committee to give full recognition to the scientific expert in the Civil Service, and proposed in effect that he should take his place on level terms with the administrative expert and the financial expert, and have his say in the formulation of policy as in the control and execution of the routine operations.

There is thus at least one instance of public recognition of the principle that a technical man who has shown that he possesses administrative talent should be eligible for other appointments. Meanwhile progress is slow. In the Local Government Service, as has been pointed out in the P E P report and elsewhere, little or no attempt has been made to implement the recommendations of the Hadow Report of 1934 regarding the recruitment, training and promotion of local government officers, and Sir Ernest Simon is still able to direct attention to our neglect of the universities in recruiting for this service, to the absence in many of our local rulers of the scientific quantitative thinking which is the basis of wise action in social affairs, and to the need of selecting and promoting men with a single eye to the highest degree of administrative ability. Here, no less than in the Civil Service itself, is there scope for the recruitment of administrators with a wider culture that embraces a real and intimate understanding, acquired from study, of the significance of science and scientific discovery in the evolution of modern society.

The contribution of the scientific or technical expert in every sphere of life grows more and more important, and the security of society makes it imperative that his services shall be fully and wisely used. Equally the burden upon the administrator grows heavier, and we can less than ever afford to miss the rare administrator of first-class ability wherever he may be found.

Origins and Growth of Chemistry

A Short History of Chemistry
By Prof. J. R. Partington. Pp. xiv + 386. (London: Macmillan & Co., Ltd., 1937.) 7*s*. 6*d*.

THE history of chemistry, like that of Ko-Ko, "may rank with most romances", and lends itself perhaps too easily to the picturesque rather than to the accurate style of narration. As Dr. Sarton has recently observed, however, "accuracy is as fundamental in the historical field as in the scientific one, and . . . has the same meaning in both fields"; so that we may properly require an unswerving adherence to fact as the prime qualification of a historian of chemistry. The second qualification must be a first-hand acquaintance with as much as possible of the original literature and a critical familiarity with secondary authorities, while the third—of equal indispensability—is a sound knowledge of chemistry from the practical point of view. All these qualifications Prof. Partington possesses, happily backing them with a pleasant style and thus softening, without in the least obscuring, a precision of thought and an economy of words that might otherwise have appeared somewhat prim. That he has attained his expressed aim of being objective, impartial, and innocent of conventional platitudes, will be agreed by everyone who reads his present book, which affords a survey of chemistry from the earliest days to the first decades of the twentieth century.

After a preliminary chapter on ancient metallurgy, glass-making, and kindred arts, Prof. Partington deals with the origins of chemistry *qua* chemistry, adopting the generally accepted view that the birthplace of the science was Alexandria. He then describes, very briefly, the diffusion of alchemy in Arabia, India, China, and Europe. This chapter could well have been enlarged without upsetting the balance of the book, but even in its succinctness it makes clear what is not always understood, namely, that early Chinese alchemy of the centuries immediately preceding the Christian era dealt mainly with the medicine of immortality, in contrast to the transmutatory alchemy of the West, out of which chemistry arose. Incidentally, it may be remarked that Prof. Partington seems to be under some misapprehension about the "Sabeans" of Harran. The Syrian heathens of this celebrated ancient town called themselves Sabæans to avoid persecution from the Caliph Al-Ma'mun; the true Sabæans or Mandæans lived between Basra and Wasit, that is, in the region formerly known as Chaldea.

With the rise of iatrochemistry, Prof. Partington's treatment becomes fuller, and he rightly devotes several pages to the work of that accomplished chemist Johann Baptista van Helmont (1577–1644), who invented the word "gas", made extensive use of the balance in his scientific researches, expressed clearly the law of the indestructibility of matter, and emphasized that metals when dissolved in acids are not destroyed but can be recovered by suitable means. The scientific spirit was reaching adolescence, though even van Helmont believed in alchemy, and gives, indeed, one of the most circumstantial accounts of a transmutation to be found in the whole of alchemical literature.

In the late seventeenth century, and throughout the eighteenth century, the phenomena of combustion formed the focal point of chemical investigation, which had at length shaken itself free from alchemy and from subservience to medicine. Boyle (1627–1691) explained the increase in weight of metals on calcination by assuming the fixation of ponderable particles of fire, though he seems to have suspected, in certain cases at least, that the increase might possibly be due to something taken by the metal from the air. The progress made by Boyle, Hooke, Mayow and others towards a satisfactory explanation of combustion was, however, interrupted by the "false theory" of phlogiston, of which Prof. Partington gives a very clear description (though it may be argued that the adjective *false* cannot be strictly applied to a scientific hypothesis or theory—*inadequate* is less open to objection). The fall of phlogiston, through the discoveries of Priestley, Cavendish, Black and Scheele and their reinterpretation by Lavoisier, leads us on to the great days of the early nineteenth century and the foundation of modern chemistry; Dalton and Davy, Berzelius and Gay-Lussac occupy the stage, and perform Herculean deeds of intellect. The materials for the historian now become embarrassingly rich, and perhaps only those who have tried to write the chemical history of the last century and a half can fully realize the magnitude and complexity of the task.

Prof. Partington has chosen what seems to be the only method of treatment suitable for a limited space; that is, to take individual topics or individual branches of chemistry and consider them separately, showing, however, their interconnexion wherever it is possible to do so. He devotes, for example, two or three chapters to organic chemistry, one to the theory of valency, another to physical chemistry, and the final two to the periodic law and the structure of the atom respectively. His account of substitution and the unitary and type theories is remarkably lucid for such an involved subject, and the chapter on physical chemistry is equally good. But the method has its disadvantages: it is bound to occasion some lack of coherence and to give greater prominence to the trees than to the wood, while in this particular case it has led to a noticeable neglect of the progress of general inorganic chemistry—the only serious fault in an otherwise excellent book.

There are very numerous portraits and other illustrations; summaries of, and supplements to, most of the chapters; biographical sketches; a bibliography; and indexes of names and subjects. The most striking feature of the book, however, is the skill with which the author makes his reader feel the æsthetic appeal of chemistry. A chemist may be "a poet who has taken the wrong turning", but Prof. Partington will convince us that the turning was not so very wrong—and did not Wordsworth send some of his poems to Davy for criticism?

E. J. HOLMYARD.

Archæology in South Africa

Mapungubwe:
Ancient Bantu Civilization on the Limpopo. Reports on Excavations at Mapungubwe (Northern Transvaal) from February 1933 to June 1935. Edited on behalf of the Archæological Committee of the University of Pretoria by Leo Fouché. Pp. xiv+183+44 plates. (Cambridge: At the University Press, 1937.) 50*s*. net.

THE treasure-seeker has often been the enemy of real archæology. Yet sometimes, like the honeybird, he has revealed the path to those wiser and better instructed than himself. So it has been with the romantic story of Mapungubwe. Five farmers in the northern Zoutpansberg district set out to explore a lonely hill in the wildest and most desolate part of the Transvaal. To the natives it was known as the "Hill of the Jackals", and they regarded it with superstitious dread. It was sacred to the Great Ones among their ancestors. The five adventurers started to dig, and found close under the surface a skeleton with numbers of gold bangles, a bowl of gold plating, and parts of a gold-plated headrest, together with small figures of rhinoceroses in gold plating. The total weight of gold in this single find was 75 ounces.

Fortunately, two of the farmers were men of education, and the younger of these two was a graduate of the University of Pretoria. He, very wisely, reported the whole history to his former college professor, and the result eventually has been the scientific expedition of which a first preliminary record is published in this beautiful volume, splendidly illustrated with photographs, coloured plates, and a series of workmanlike plans and diagrams.

It must have been a proud moment for Mr. Van Graan when he learned that the Prime Minister, General Hertzog, had declared the exploration of Mapungubwe to be "a matter of national importance". General Smuts, then leader of the Opposition in Parliament, showed also the keenest interest. So that, in 1933, the Government bought the farm outright, and made an agreement with the University of Pretoria by which the University should undertake to excavate for five years, receiving from the Government two pounds for every pound raised by its own efforts. There was then formed the Archæological Committee of the University of Pretoria, on which the Government, the public, and the University were all represented. The City Council of Pretoria and various private citizens immediately contributed a substantial sum, with which operations were begun in June 1933.

The whole history of this undertaking and its reception by the Government and the general public is most inspiriting. It shows a degree of enlightenment as rare as it is admirable, and may stand as a great example for other and older countries. South Africa, indeed, has always been alive to the importance of its antiquities. It was Cecil Rhodes himself who saved Zimbabwe from the destroyer, and the Chartered Company soon afterwards appointed a custodian for the principal ruins in its own territory. Both Rhodesia and the Union have passed in recent years very effective laws for the preservation of their archæological heritage.

It was, perhaps, inevitable that, thirty or forty years ago, when Southern Rhodesia was still a new country, the zeal of untrained explorers should outrun their discretion. Excavations at Zimbabwe and other sites about the turn of the century and for some years afterwards were very badly conducted, and much evidence was unwittingly destroyed by those whose official duty it was to conserve it. Since 1905, however, this has been remedied, and only competent workers are allowed. Nevertheless, gold seekers, adventurers, and others had destroyed so much in Rhodesia, where the finest ruins are situated, that it is most fortunate that outlying stations of the same culture have been discovered in the bordering countries, in Portuguese territory on the east, and on the southern banks of the Limpopo in the Transvaal. These, though outwardly less spectacular, may be expected to add very greatly to the sum of evidence, and ultimately to provide the complete solution of the problem.

For it is now generally recognized that Zimbabwe is by no means unique ; it is only the most striking and the most sophisticated example among a large number of stone-walled kraals belonging to a medieval and post-medieval Bantu culture. While the earliest of these may very possibly have been founded about the ninth or tenth century after Christ, the majority were at their most flourishing stages in the sixteenth and seventeenth centuries. Mapungubwe is dated to about 1500 ; neighbouring sites noted in this volume are later, and it is well established that the culture persisted in many places until it was destroyed by the Matabele invasions of the nineteenth century.

I have reason to remember that the opinions just expressed were very unpopular thirty years ago, though even then they were shared by many of those who knew the country and the natives best. But the work of several unprejudiced students, among whom should be especially mentioned two contributors to this volume, Mr. Schofield and the Rev. Neville Jones, has greatly changed the viewpoint of even the least scientifically minded. Miss Caton-Thompson's researches in 1929 routed the last desperate adherents of the Queen of Sheba, and it may now be considered that the "Oriental mirage" has disappeared for ever. Student and settler alike now realize that the Zimbabwe cultures represent the history of native African peoples in a period contemporary with medieval and modern history in Europe. In such a changed atmosphere we may look forward to a great development of knowledge analogous to that which has taken place in America in the last half-century. Only forty years ago the world had very slight and inaccurate knowledge of the great civilizations of the Mayas and the Aztecs. Mists of fantasy and wild speculation enwrapped them also. But now excavation and study have made the archæology of Central America a part of the established history familiar to every cultured man. There is no reason why the African Monomotapa should not be as familiar to our grandchildren as Montezuma has long been to ourselves. He is quite as authentic, and was probably quite as important.

Not only to South Africans, but also to all who are interested in a most fruitful and promising field of history and ethnography, this admirable book may be warmly recommended. It is rightly and properly technical, written with the greatest economy of words, and with little elaboration of theory, but it describes its material thoroughly and exhaustively with a completeness and precision that leave nothing to be desired. Especially worthy of attention are the minute discussion of the pottery by Mr. Schofield, and the excursus on beads by Mr. H. C. Beck, the highest living authority on that subject. The description of the field work by the editor and by Mr. Neville Jones shows that South African excavators completely understand their problems, and are using their local knowledge as well as the experience of excavators in other fields to develop a technique suitable to the rather peculiar local conditions.

D. RANDALL-MACIVER.

The Presentation of Applied Physics

(1) Elementary Engineering Science
By Dr. Arthur Morley and Dr. Edward Hughes. Pp. xi + 290. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1937.) 3*s*. 6*d*.

(2) Engineering Science
By H. B. Brown and A. J. Bryant. Vol. 1: Mechanics and Hydrostatics. Pp. xv + 403. (London: Macmillan and Co., Ltd., 1937.) 5*s*.

(3) Further Mechanics and Hydrostatics
By A. W. Siddons, K. S. Snell and N. R. C. Dockeray. Pp. viii + 184. (London: Edward Arnold and Co., 1937.) 3*s*. 6*d*.

(4) Physics for Technical Students:
Mechanics and Heat. By Prof. W. B. Anderson. Third edition. Pp. ix + 378. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 15*s*.

(5) Physics in Industry
By Karl T. Compton, E. C. Sullivan, Zay Jeffries and E. Q. Adams, Paul D. Foote, J. P. Den Hartog, John Ely Burchard, Oliver E. Buckley, Clark B. Millikan, Joseph Slepian, Homer L. Dodge, A. R. Olpin. Pp. xiv + 290. (New York: American Institute of Physics, 1937.) 1.50 dollars.

"SCIENCE increases the power of the rulers, giving them control over the sources of modern life. A wise nation, a people who intended to remain free would get to know all about science too." These words recently appeared as a random note in a daily newspaper and if there is one branch of science to which, in particular, they could be taken to refer, that branch is physics, with its many practical applications. Each of the books quoted above deals with one or more aspects of applied physics, and each, in its way, aims at promoting its study. Their perusal leaves a strong impression of the stultifying influence of the examination system — teachers, students and writers being cabined, cribbed, and confined within the limits of the syllabus chosen.

(1) In the first example, the National Certificate code provides the limitation, by which term is to be understood such restriction of view as is ensured, in a physical sense, by the blinkers in the harness of a horse so that he may see no more than lies directly ahead. The book provides a course of instruction in engineering science for students in the first year of their preparation for the Ordinary Certificate in Mechanical or Electrical Engineering and, as such, it is a very good course consisting mainly of elementary mechanics with a modicum of heat and electric technology.

The basis of the treatment is the principle of work, which certainly provides an easy approach, but the book suffers from the effects of compression, as, for example, in the condensing of a phrase until it lacks precision. To the teacher, it will certainly be useful as the foundation of a session's work.

(2) Messrs. Brown and Bryant's book on "Mechanics and Hydrostatics" is somewhat more advanced and includes two years' work for the Ordinary National Certificate and sufficient preparation for preliminary professional and entrance examinations. The authors have adopted an easier style and have freely used such elementary mathematics as is necessary for the adequate presentation and solution of problems. The treatment is based on a scheme of experimental work, which is fully outlined, and throughout the book reference is made to practical examples.

The clarity of the argument and the excellence of the diagrams make it likely to prove a helpful text-book in the early stages. The later chapters on strength and testing of materials, hydraulic machinery and the mechanics of fluids provide excellent preparation for the higher stages.

(3) It is for a different class of student that Messrs. Siddons, Snell and Dockeray have prepared the series entitled "Mechanics", of which the present volume constitutes the third part. It meets the needs of those who are in the early stages of their preparation for the Mechanical Science Tripos at Cambridge or for higher mathematics in the Army Entrance Examinations. Here a much more academic treatment of the subject is adopted, and readers require a sound knowledge of mathematics including some calculus. The formal method of presentation will be found very suitable for those students who have had a well organized and directed education and have been trained to study methodically.

(4) While each of the three preceding books is good in its way and within its limitations—which are those of examination syllabuses—and may be accepted as a reliable medium of instruction, they lack enthusiasm. They work methodically and conscientiously through the allotted task, but will not evoke in the student a wider interest in the subject. In sharp contrast, Prof. Anderson takes up his subject with an obvious sense of its importance and of its absorbing interest. While writing for students of science, agriculture, engineering and other branches of applied physics, he urges its cultural value to all. This is not to suggest that his treatment departs from the logical and recognized course, but rather to indicate the spirit in which the instruction is given and the easy introduction of practical topics to illustrate and reinforce it. For example, after dealing with fluids in motion and reduction of pressure with increase of velocity, he leads up to a discussion on carburettors, ship collisions, pitot tubes, the rotor ship, venturi meters, steam injectors, organ pipes and several other examples. With such a book the student will gain greatly in his mental outlook.

(5) The last of these volumes is in a different category. It contains a symposium of essays on the applications of physics in industry by different American authorities in the glass, metal, oil and other industries. Though by no means equal in quality, they all, with perhaps one exception, reach a high standard of interest and of technical value. It is a book which should be read not only by every scientific worker and engineer but also very widely by the general public, to whom it would convey the vast importance of physical science in modern life.

Analysis of Animal Foods

The Structure and Composition of Foods
By Dr. Andrew L. Winton and Dr. Kate Barber Winton. Vol. 3 : Milk (including Human), Butter, Cheese, Ice Cream, Eggs, Meat, Meat Extracts, Gelatin, Animal Fats, Poultry, Fish, Shellfish. Pp. xxv + 524. (New York : John Wiley and Sons, Inc. ; London : Chapman and Hall, Ltd., 1937.) 40*s*. net.

WHEN the two preceding volumes of "Winton and Winton" were issued, we believed, as did the authors, that the third volume would complete their work. Apparently, however, they had under-estimated the range of products needing survey, and they have now had once more to postpone the end of their labours. The publishers state that volume 4, in preparation, will cover the remaining foodstuffs—sugar, syrup, tea, coffee, cocoa, spices, extracts, etc. Volume 3, however, will be for many the climax of this important and useful work, for the analysis and control of animal foods offer, broadly speaking, greater difficulties to the technologist than do even some of the knottier problems in the control of cereals and seed oils.

Books of this type must always suffer from one inherent disadvantage. In this volume, for example, it must have been very difficult to decide exactly how much space to allot to milk and milk products ; actually they receive 209 pages. Eggs (in Part 2) occupy a further 50, miscellaneous animal products some 30, meat and meat products just under 140, fish and fish products a further 50. The remaining pages are devoted to batrachians and reptiles and to an index.

It is clear that 200 pages about milk and milk products constitute, in effect, a monograph on the composition and analysis of dairy products—matters that have been very adequately treated in a number of specialized books. Is there really any call for its treatment at such length here ? If, on the other hand, it had been decided that much shorter treatment would be satisfactory, the authors would immediately have laid themselves open to the charge of inadequacy.

We must admit that this is a problem that we are glad not to need to face. The authors, however, have had to face it and, granted the premises that decided their editorial policy, have done so with considerable success. It is, of course, impossible to check anything but random samples of the facts summarized in such a book. References appear to be brought up to 1936, and include such recent information as the Levene formulæ for yeast nucleic acid and thymus nucleic acid, and for inosinic acid.

The book is unfortunately not free from gross printer's errors. For example, "Greatine" on page 275. Also, much of the information collected by the authors about the effect of cooking on meat (and other foods) has now been rendered obsolete by the studies of McCance and Widdowson. Nevertheless, the book will remain permanently useful, not only as a record of facts, but also as a record of the kind of facts that have been recorded.

The Conquest of the Stratosphere

By Chas. G. Philp. Pp. ix + 205. (London: Sir Isaac Pitman and Sons, Ltd., 1937.) 7*s*. 6*d*. net.

MR. PHILP'S two books are of very different value; their defects are alike, their merits dissimilar. Both are marred by a superficial and far from accurate handling of scientific facts and hypotheses, and both suffer from that adjectival rash which infests so many works of popular science—"hazardous risks", "intrepid explorers", "unknown regions", "entrancing story", "astounding information", "tremendous height" and so on. As for "evaporizing", "stratonaut", "astronautist"—what words!

The merits of "Stratosphere and Rocket Flight", which was published some time ago, lie in its exaggerations, its failure to present a fairly balanced picture of the great practical difficulties that must be overcome before the great theoretical possibilities of reaction propulsion are converted into directed achievement. They are merits, because they are sufficiently obvious to a reader of the most modest intelligence, and because they will compel the reader to think and question at every page. "The Conquest of the Stratosphere" opens inauspiciously with a chapter in which our incomplete knowledge of the atmosphere is presented in obsolete and misleading form. Scientific facts and the scientific results of stratospheric flight are not presented in a form which will convince the average reader that justification of the pains is yet in sight.

But a clear majority of the pages are devoted to vivid and straightforward description of each of the historic manned balloon flights into the stratosphere, from Glaisher and Coxwell in 1862 to Stevens and Anderson in 1935. The stories, which are mainly based on a close (sometimes too close) following of the actual logs, are absorbingly interesting, and the modest price of the book is handsomely earned in this connected narrative of exploration. It can be most cordially commended to everyone who needs reassurance that grandeur can still in the twentieth century be attained in communal organization and in individual courage, freed from passion and self-interest. For those not yet tormented by philosophic doubts and fears, it is a fine story book.

Insects of the British Woodlands

By Dr. R. Neil Chrystal. Pp. xiii + 338 + 33 plates. (London and New York: Frederick Warne and Co., Ltd., 1937.) 7*s*. 6*d*. net.

THIS book is intended primarily for those who are concerned with the management of British forests and woodlands. Through the operation of the Forestry Commission, extensive tracts of land have been taken over in Britain for planting with forest trees. These trees include both native and alien species and, as the work goes forward, increasing attention will be directed to their various insect enemies. There has been a very evident need for a good practical manual on the insect enemies of the forester and, in fact, of trees in general. Such a work requires to be up to date and treat of the insect concerned in close connexion with methods of forestry practice.

This want may be regarded as being adequately met by the present book. Those who use it will find sufficient introductory matter to become acquainted with the essential features of insect biology and structure. They will also be able to name, without undue difficulty, the more important insects encountered and, at the same time, gain an insight into their habits and relation to forestry. The various conditions and circumstances which govern insect outbreaks in woodlands are explained: both natural enemies and artificial methods of repression are clearly discussed, while simple methods for the collection and study of insects are given.

Written by an author who has had much first-hand experience with the subject, the book provides the sort of information that is required. It is not overburdened with technicalities, and the clear, straightforward style in which it is written should commend it also to the notice of nature study teachers and others interested in insect life. It is well and fully illustrated and very reasonably priced.

A. D. I.

Sound-Recording for Films:

a Review of Modern Methods. By W. F. Elliott. Pp. xi + 134 + 12 plates. (London: Sir Isaac Pitman and Sons, Ltd., 1937.) 10*s*. 6*d*. net.

THE accuracy of aim, clarity of conception, and exactness of expression which characterize Mr. Elliott's work are well illustrated in its title. His book is not one on "Sound Recording on Film", with detailed description of the physics and chemistry of the sound track and the related apparatus. It is a shrewd and stimulating discussion of the art of that highly skilled, imaginative, ingenious, agile and patient collaborator in film-making who bears the regrettable though comprehensible title of "recordist". A very few inexactitudes and obscurities in the brief references to acoustic physics are quite unimportant in a book full of wisdom, common sense and sound artistic judgment.

Although it is designed as a practical guide to the technician, the book is of a much wider interest. Its claim to be the first of its kind is justified, and it should be read not only by every recordist but also by every director. The general reader will find it enthralling and illuminating. He will get a fair impression of one aspect of that almost incredibly onerous labour, that meticulous care, and that more than humanly patient iteration which goes to the making of a good film, and of which direct evidence must be completely absent from the good film.

Nearly everything that Mr. Elliott says is so right that there is a temptation to call it obvious. A visit to an average film show will cure the temptation, and will renew the feeling that such a visit must be a somewhat painful experience for Mr. Elliott and for any recordist of his high quality and ideals.

A word must be said for the ingenious "post-synchronization" of the dust-cover, which shows on the front a typical film scene and on the back the battery of technical aids which stands—in this case literally—behind the scene.

Iodine*

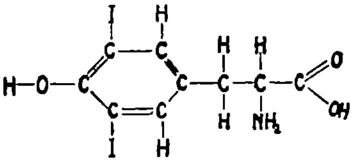
By Prof. Irvine Masson

OF the two aspects of iodine and its chemistry which are here surveyed, the first is that of the part played by the element in terrestrial economy, whether inorganic or organic or both. In the total make-up of the earth, iodine is not one of the fourteen elements which compose 99·95 per cent of the mass, but is one of the rarest of the non-metallic elements. Nevertheless, it is scattered almost everywhere, in minute traces ; a ton of average rock contains some 300 milligrams, a ton of sea water about 17 milligrams.

The chemical reactions of geology have very rarely segregated any of these widely dispersed traces ; there are scarcely any minerals containing iodine as an essential constituent, and the few that have been found are out-of-the-way mineralogical curiosities, small specimens rather than deposits or ores. Only in one place in the world have solid iodine compounds come together in quantity, and that is in the nitrate deposits of Chile, high up against the western slopes of the Andes. There the element occurs as inorganic iodate, and there are uncounted thousands of tons of it. Yet, even so, the iodate is not by itself in veins or beds, but is simply one of the minor impurities in the great accumulations of sodium nitrate. We might be able to explain how the iodate got there if we knew how the nitrate had got there ; but, in spite of much interesting work, all that seems really safe to say about the origin of Chile nitrate is that no single hypothesis has yet met all the known facts. What is indubitably true is that the world's commercial supply of iodine (with trifling exceptions) comes from the Chile nitrate factories, from which it is exported at the rate of nearly 1,000 tons of the element yearly.

It seems from these facts that during the 2,000 million years which span geochemistry, iodine has played a part that was practically nothing, and that had the element never been created, the inorganic earth would not be appreciably different from what it is. But with the origination of organic life (800 million years ago, or earlier), iodine began to matter. First it became not wholly dispersed, but partly to be segregated from solution in the sea into the colloids of living organisms floating there. Then, as the forms of living things developed, the iodine was not only taken up into them, but also became a chemical part of some of them. They developed still further and more variously ; and now, the vertebrates, and we ourselves, could not continue without iodine, either as individuals from month to month or as species from generation to generation.

Looking more closely into this from a biochemical point of view, we learn from many recorded analyses of vegetable and animal materials that three living creatures stand out far beyond the rest as being rich in iodine. These three are seaweeds (brown and red), bath sponges, and certain classes of corals. One of these is vegetable, two are animal, but all three are marine ; and this is so notwithstanding the fact that the sea water is excessively poor in iodine compared, for example, with many soils and most rocks. The iodine content of these organisms is thousands or even millions of times more than in the sea water in which they live ; it may reach one half per cent of the weight of the dry tissue in seaweed, one per cent or more in the sponges, and in a coral as much as eight per cent. The chemical form of this iodine is undecided in the case of seaweed ; but as to the horny sponges and horny corals, the work of Drechsel (1896) and of Wheeler and his associates (1905–7), confirmed by that of Mörner (1907–13), showed, surprisingly, that the skeletal protein releases its iodine as the definite aromatic amino-acid, 3 : 5 di-iodo-tyrosine :



3 : 5 DI-IODO-TYROSINE

It is improbable that this substance is supplied to the animal cells ready-made in their plant food ; such food no doubt brings them the common protein ingredient, tyrosine, but the iodination would seem to go on in the cell. For this purpose, the very minute traces of dissolved inorganic iodine salts in sea water are drawn upon ; and if these are iodides, the co-operation of an oxidizing agent is obviously necessary (an oxidase naturally suggests itself). The direct iodination of tyrosine in the laboratory, with elementary iodine as the reagent, was easily accomplished by Oswald (1909) and has lately been studied in more detail, as a part of protein chemistry, by Bauer and Strauss (1935).

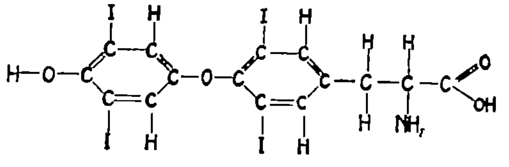
---

* Substance of a Friday evening discourse at the Royal Institution, delivered on December 3, 1937.

It is particularly to be noted that organic halogen compounds of any kind are extraordinarily rare among natural products. The only other cases known at present are: di-bromo-tyrosine, obtained by Mörner (1913) from horny corals, and evidently formed in the same way as the di-iodo-compound; di-bromo-indigo, the classical Tyrian purple dye from the glands of the shellfish *Murex* or *Purpura* (Friedlander, 1909, 1922); certain aromatic chloro-compounds lately isolated from lichens (Nolan, 1934; Pfau, 1934); and other chloro-compounds which, as Raistrick has shown (1936), are formed by certain moulds growing in solutions of inorganic chloride.

No experiments seem to have been made in order to learn whether the addition of iodine compounds to sea water, or their removal, affects the growth of those marine organisms in which iodine is found organically combined. It is worth noticing, however, that the iodine compound is accumulated not in the fleshy cell-tissue of the sponge or the coral, but in the horny skeleton on which these living cells sit; and this skeleton, though mechanically useful to the cell colony, may almost be called an excretory product of that colony. It is for the animal physiologist to decide whether in these cases the skeletal protein is serving as a mere dump for di-iodo-tyrosine that has been discarded by the cells as useless, or whether, on the contrary, it acts as a reserve store upon which the cells can draw for part of some vital process. This question, unsettled though it is, is not without significance in the light of the biochemistry of animals higher up in the evolutionary scale.

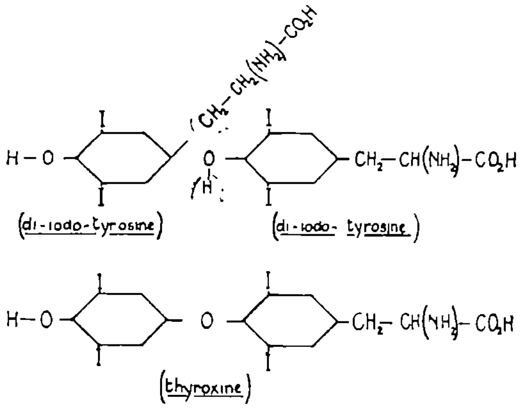
Sponges and corals are lowly creatures, with small differentiation of tissues and no co-ordination of parts, and they existed even in Cambrian times, long before forms of land life were evolved. Making, then, a very wide biological jump to the vertebrates, including man, we again find the faculty for the organic fixation of iodine, and it is localized now in the thyroid gland. That it here determines the metamorphosis of amphibian larvæ, such as tadpoles and axolotls, was first shown in 1912; and the well-established correlation of inadequate traces of iodine in food with irregularity in the function of the gland, and consequently with the disturbances of basal metabolism which cause goitre, imperfect growth, myxœdema, or cretinism, was given a rational basis first by Kendall's isolation (1915) of the thyroid hormone as a crystalline organic iodine compound which he called thyroxine, and then by the brilliant work of C. R. Harington and his associates (1926 *et seq.*), to whom we owe our knowledge of what thyroxine really is.



THYROXINE

It appears that the iodine atoms in this molecule are essential to the physiological potency of the substance; and a teleologist might well find in this hormone molecule the sole *raison d'être* of the element iodine.

Harington has shown that thyroid iodine is present partly as thyroxine but also as di-iodo-tyrosine, both amino-acids being chemical components of the complex protein thyroglobulin. The direct physiological activity of the di-iodo-tyrosine appears, so far as published evidence goes, to be relatively slight; but there cannot be much doubt that it is the precursor of thyroxine in the chemical synthesis for which the thyroid gland is responsible. The conversion into thyroxine, indicated in a purely formal way by



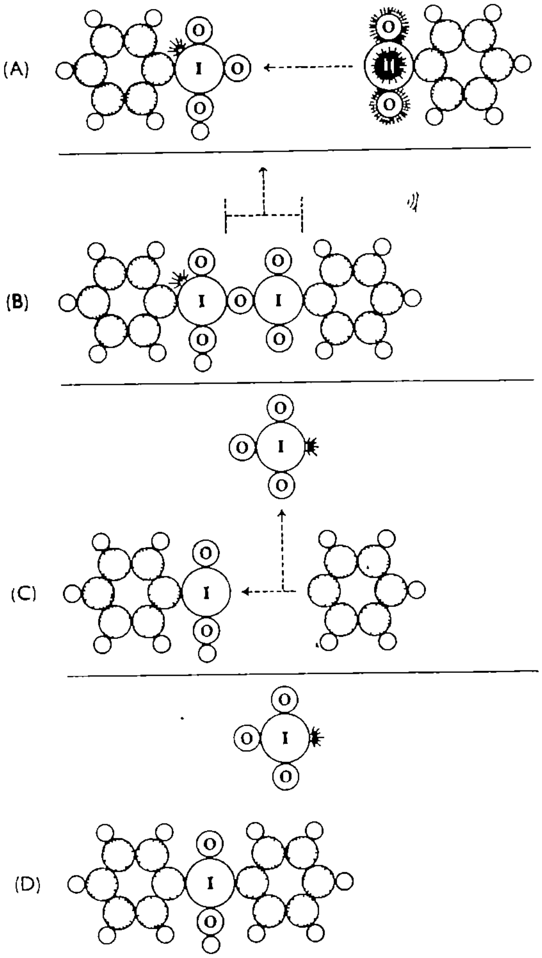
has not been accomplished in the laboratory (the pioneering synthesis of thyroxine by Harington and Barger necessarily used materials and methods not natural to living tissues), but it would involve steps of a kind not unknown in other branches of protein chemistry.

To sum up this part of our subject: the opportunity for the natural fixation of inorganic iodine into an organic form has in all ages been extremely slight; not because the process is intrinsically difficult (for it is not), but because the supply of inorganic iodine has always been extremely scanty. Accordingly, iodine is not one of those elements which, like sulphur or phosphorus, became normal ingredients of common proteins. Living things had next to no iodine to draw upon, so most of them managed and evolved without it. But very early in the history of multicellular animals in the sea—if we may make an inference from those simple forms which have survived into this age—the organic fixation and accumulation of iodine was accomplished by some of them, and what they did with it was to make it into di-iodo-tyrosine. This same faculty of making di-iodo-tyrosine, we find, has been preserved, or at any rate repeated, by the vertebrate animals, localized in their thyroid glands. Besides that faculty, we have put our finger upon one further chemical step, which has apparently accompanied the evolution of the vertebrates, is characteristic of them, and is indispensable to their being: namely, the final conversion of di-iodo-tyrosine into thyroxine.

That iodine is a biochemical element is a fact which lends importance to its organic chemistry in general; and in what follows, one part of this will be discussed, namely, that in which organic iodine is multivalent. In this field, some is not new but is perhaps undeveloped, while the rest is new; and to illustrate it, we shall confine ourselves here to a few connected examples drawn from work done at Durham (*J. Chem. Soc.*, 1669; 1935. 1718; 1937. NATURE, 139, 150; 1937). Throughout, the chemist has to bear in mind that iodine is not merely the heaviest halogen, but—especially when multivalent—is also the terminal member of its series in the Periodic System, and its behaviour is to be regarded accordingly.

Victor Meyer and Wachter's discovery of iodosobenzoic acid (1892) prompted Willgerodt to study iodobenzene dichloride, which he had isolated seven years before, and so to discover iodosobenzene and, ultimately, many other aromatic iodoso-compounds. Besides behaving as bases towards acids, these derivatives of tervalent iodine exhibit self-oxidation-reduction, as do nearly all inorganic compounds in which a halogen atom is in an intermediate state of valency; so iodosobenzene spontaneously turns into iodo- and iodoxybenzene, which latter compound has reactions of general chemical interest.

Iodoxybenzene, $C_6H_5IO_2$, is not only formally analogous to nitrobenzene, $C_6H_5NO_2$, but also by its chemical behaviour shows the internal electrical polarity which is known, on a variety of evidence, to exist in nitrobenzene. The respective donor atoms iodine and nitrogen are positive, the acceptor oxygen atoms are negative. Hence an iodoxy-compound is attacked either by negatively charged ions or parts of other molecules, which its positive iodine attracts, or else by positively charged ions or groups, which its negative oxygen atoms attract. In nitrobenzene, the small donor nitrogen atom is screened by the phenyl and by the two oxygen atoms, and is therefore not exposed to negatively charged reagents as is the large iodine; but its negative oxygen atoms are open. Thus, both compounds form salts with strong acids, by the co-ordinating (with resonance) of a proton with their oxygen atoms; for example, the crystalline hydrogen-sulphates:



Drawings of four successive stages of a model showing the expulsion of the iodate ion. The diagram illustrates the general nature of the other models also. The backgrounds were black. Positive ions were marked by the emission of a bright red light from the group of atoms; negative ions by that of a bright blue light (indicated by a small conventional 'explosion' sign). Polarities within molecules were shown by a red glow over the disk of a positive (donor) atom and a blue glow over the disk of a negative (acceptor) atom, as suggested in the drawing of the molecule of iodoxybenzene on the right in the first stage.

$[C_6H_5IO_2{\cdot}H]^+ [HSO_4]^-$	$[C_6H_5NO_2{\cdot}H]^+ [HSO_4]^-$
Iodoxybenzene hydrogen sulphate.	Nitrobenzene hydrogen sulphate.
(Cryst., mp. 127°)	(Cryst., mp. 12°)

Iodoxybenzene dissolves in alkali, owing to the attachment of a negative hydroxyl ion to the positive iodine, yielding the unstable solute, the *phenyl-iodoxylate* of the alkali metal:

$$\begin{array}{ccccc} C_6H_5IO_2 & + & Na^+(OH)^- & \longrightarrow & Na^+[C_6H_5\,IO_3H]^- \\ \text{Iodoxy-benzene} & + & \text{Sodium hydroxide} & = & \text{Sodium phenyl-iodoxylate} \end{array}$$

Nitrobenzene, for the reason explained above, does not combine with alkali; but the arylphosphonic and arsonic acids are probably analogous to the iodoxylates.

When the solution of an alkaline iodoxylate is boiled, its complex negative ion extrudes the group IO_3 which, as the iodate ion, carries off the ionic charge, leaving behind benzene:

$$C_6H_5IO_3H' \longrightarrow IO_3' + C_6H_6.$$

This elimination of the iodate ion is characteristic of such substances, especially in alkali. Thus, in a cold iodoxylate solution, the complex ion spontaneously co-operates with dissolved iodoxybenzene to do so, and the residues couple to form *diphenyliodyl hydroxide* (or its alkali salt), with the structure of which one may compare the diaryl phosphinic and arsinic acids:

$$PhIO_2 + PhIO_3H' \longrightarrow IO_3' + Ph_2IO.OH.$$

Again, the same dominant tendency is seen in the formation of iodonium compounds by Victor Meyer and Hartmann's second method, where iodoso- and iodoxy-compound react together in an alkaline medium:

$$RIO_2 + RIO \longrightarrow IO_3' + R_2I\cdot.$$

The converse of these processes, that is, the return of iodine from inorganic iodate into the organically combined state, proves easy to realize in the laboratory, under conditions of high acidity, organic derivatives of multivalent iodine being formed.

It will be understood that in these examples of reactions (all of which, in the discourse of which this is a condensation, were illustrated by working scale-models showing the atomic and electrical exchanges), the detailed intermediate mechanisms have here been slightly simplified, especially as regards the organic parts of the groups concerned. In them, however, the primary point is rather the formation and existence of hitherto unknown types of iodine compounds. These lead to a new field of chemical inquiry, and help to show, as do the biochemical facts reviewed, that we must think of iodine as an element which, like nitrogen or arsenic, is not inorganic alone, but is emphatically an organic element also.

Scientific Research in India

From a Correspondent

THE activities of the scientific delegation in India were by no means confined to the proceedings of the Congress in Calcutta and to sightseeing. Every opportunity was taken by individual members or groups of members to inform themselves of the progress of science in the various institutions which occasion could be made to visit. The notes which follow cannot be exhaustive, as they are based upon information only from members of the party who have just returned to England in the S.S. *Strathaird*; a substantial number of the delegates are not yet home.

The discovery of the pre-Aryan civilization of the Indus basin has stimulated studies in Indian archæology, and the delegation was profoundly impressed by the care bestowed upon the famous frescoes and sculptures in the rock-hewn temples at Ajanta and Ellora, while excavation is in progress elsewhere in the dominions of H.E.H. the Nizam of Hyderabad. The museums at Delhi, Bombay, Sarnath (near Benares), Calcutta and Madras all possess notable treasures, and that at Calcutta especially needs much greater space for its adequate exposition in order to guide future excavation. Turning to work within the scope of present-day anthropology, the Brahmachariya Sangha founded by the late Maharajah of Kazimbazar illustrates a type of Indian organization designed to help especially aboriginal peoples to overcome handicaps due to lack of knowledge of Hindu or Dravidian languages and to general backwardness. The aborigines around Ranchi on the Chota Nagpur plateau are being taught on the basis of a modernist interpretation of the Vedas, and schools, clinics and legal aid come within the province of this organization.

Elsewhere, the great medical institutions naturally attracted attention. At the famous Haffkine Institute in Bombay special note was taken of the work in progress towards a theory as to outbreaks of plague after periods of immunity; it was learned incidentally that mice are found more suitable than rats for plague experimentation. The work on rabies was also remarked; and it was observed that in Bombay malaria has been reduced to almost negligible proportions by covering in all open water tanks with fine-meshed wire netting or with glass. The School of Tropical Diseases at Calcutta is worked in connexion with the hospital, where there are beds for keeping cases under prolonged study and treatment. The All India Institute of Hygiene and Public Health possesses fine premises, but there appears as yet to be a shortage of expert workers ; and it may be remarked here that a more extensive supply of current medical and scientific journals, English and foreign, is apparently needed in medical libraries. It was satisfactory to note the increasing number of women's hospitals, staffed by women, especially in such a land as India, where so many women are debarred from medical aid unless rendered by their own sex. Women doctors are increasing in number, but an adequate supply of good nurses is as yet far from assured. Medical psychology was found to be fairly well established in Calcutta, and an excellent general and educational psychology is rapidly gathering strength in Mysore. The value of industrial psychology is well recognized ; the material aspects of the science appear to outweigh the purely philosophical.

Research in agriculture, obviously of outstanding importance for India, aroused much interest. For example, at the Imperial Agricultural Research Institute in New Delhi, the results were exhibited of crossing the sugar-cane with a species of bamboo which grows to a height of 60 feet, and also with sorghum and Indian corn. This work forms a part of breeding experiments carried out in order to discover the origin of cultivated sugar-canes and to improve them by hybridization. In the chemical department of the Institute valuable work is in progress on the utilization of atmospheric nitrogen in soils. The visit to Dehra Dun gave the delegates opportunity to see something of the important work of the Forest Research Institute, in which departments are concerned not only with the problems of forestry itself but also with timber testing and preservation and the uses of wood-pulp, resins and other products. The Punjab Agricultural College and Research Institute afforded an opportunity for observing the progress of valuable economic research in various departments, which has already added much to the agricultural wealth of the province. At the University of Agra the dissemination of cereal rust fungi has been under investigation for seven years, and the foci of infection have been traced to hill-tracts where rusts remain during summer in the uredo-stage. The good work of the cotton research and textile research laboratories is well known, and in consequence the opportunity of seeing some of the results at Bombay was welcomed. Plant virus work on tobacco leaf curl and on mosaic of sugar-cane was found to be in progress at more than one centre, but none was encountered on potato virus diseases, though preparations are being made at New Delhi for a general assault on these problems by genetic methods. In connexion with animal husbandry, one of the delegates comments in the highest terms upon the work of the Indian veterinary colleges and the cattle and other breeding establishments which he was enabled to visit. In the notes of another delegate reference is made to a secondary school at Bikram, a village south of Patna, which possesses a demonstration farm partly worked by pupils in the agricultural class ; the principle appears capable of wider application.

Delegates were fortunate in being able to take part in the hundred and fiftieth anniversary of the foundation of the Calcutta Botanic Gardens, which have been directed by so distinguished a succession of botanists and have played so important a part in the development of systematic botany. The small aquarium at Madras, the extension of which is contemplated, was much admired for the interest of some of its special exhibits, for example, the sea-snakes. Some adverse comment was directed against the attendants, whose artificial stimulation of the exhibits for the entertainment of visitors was deprecated. The zoological garden at Mysore was particularly noteworthy for the care bestowed on its lay-out and upkeep and for the fine and happy condition of the inmates. It was noticed that the enclosure of the giraffes by a small ditch and a single rail about eight feet above ground seemed entirely adequate.

It is well known that the Geodetic Survey has its headquarters for mapping and fieldwork at Dehra Dun ; but reference is due here to the latitude variation station at Agra which, it is hoped, will prove to be more free from causes of systematic errors than the station previously at Dehra Dun, which suffered from poor conditions for observation owing to its nearness to the Himalayas.

It is not the object of this report to comment further upon the work of the research departments and institutions so long associated with the Governments of India ; nor can it be attempted to review all, or even any large fraction, of the work of the various universities visited by the delegation. But special reference has been made by one of the delegates to the important applications of science to industry under investigation in the chemical laboratory at the University of Lahore, which are directed primarily to the utilization of waste products. Thus, cottons are improved in appearance by treatment with colloidal solutions of certain silk-like cotton wastes, resins are recovered from oil residues, soaps are made stable in colour and perfume, waste molasses is made into tiles and insulating materials, broken rice grains of little or no value are changed into colloidal solutions and used for making synthetic rice grains, oils are purified so as to burn without smoking. Researches of a fundamental character are being made into the magnetic properties of atoms and molecules with the object of revealing the nature of chemical bonds and the control of chemical reactions. At the Tata Institute at Bangalore the experiments in the physics section on backward internal scattering of light in liquids and the effect of supersonic waves on refraction show a combination of high experimental skill and first-class apparatus. A demonstration of the structure of lustrous shells was beautiful and impressive.

Among other notes, one of the delegates was struck with the initiative shown in making apparatus, which otherwise would have been hard to come by in India, at the Central Meteorological Station for altitude observations in Agra. Another comments upon the fine work of the Hydrodynamic Research Station at Poona, where, beneath the great irrigation dam, large-scale experiments are possible and have resulted in numerous and various records covering the work of years and published by the Government of India, but yet to be incorporated, as they should be, in text-books on hydraulics.

Such are a few examples—and it must be emphasized that they are only a few among many —of the widespread and practical interest in the advancement of science and its applications encountered by the delegation in India. If the delegation, through the contacts which its members have made, has succeeded on one hand in aiding that advancement in any manner, and should succeed, on the other hand, in broadening understanding at home of the achievements of scientific workers in India, it will have discharged its most important functions for the benefit of science in both countries.

The Aurora of January 25-26

THE auroral display on the night of January 25–26 was remarkable not only for it's brilliance but also for the wide area over which it was observed. Some time must elapse before it is possible to collect complete information, but it seems certain, from the newspaper reports already published, that it was seen over practically the whole of Europe, and as far south as Gibraltar and Sicily. *The Times* of January 27 states also that vivid auroral displays were seen over a large part of Canada on the nights of January 24–25 and 25–26.

Accounts of the phenomenon as observed in the British Isles differ considerably in points of detail. It is proposed to give here a few extracts from the most precise reports received either by NATURE or by the Meteorological Office. An account of the appearances observed at Harpenden, Herts, by Dr. B. A. Keen was given in last week's issue. Dr. Keen observed the display from 6.45 until after midnight. Three periods of brilliant display were noted, around 7.45, 8.30 and 9.45. The main features noted were red glows in the north-west and north-east, with a low green arc between during the early stages, green and white rays traversing a bright red glow in the north-north-east about 7.45, and rapidly fluctuating green streamers between north-west and north-east about 9.45.

At Kew Observatory, detailed observations were made between 6.50 and 9.10. These observations show good general agreement with those made by Dr. Keen, except that a green coloration of the arcs and rays is not mentioned. Strong groups of coloured rays were observed after 7.35, and at 7.51 these were spreading out from north-north-east to west-north-west reaching elevations of 5° to 10° above Polaris. At 7.57 the glow extended slightly beyond the zenith. A few minutes later, at 8.07, the display faded completely and no aurora was visible for several minutes. The later stages as observed at Kew were distinctly less brilliant, though there were some further appearances of arcs, patches and rays.

Mr. Charles Leaf sends details of observations made near Cambridge from 1.15 on January 26. He writes as follows :

"As seen at 1.15 G.M.T. there was a bright greenish glow behind banded cirrus cloud right across the northern horizon, while just to the north-west of the zenith there were two parallel bands of delicate pinkish light. Short groups of rays frequently developed in these bands. The rays were paler than the bands themselves, and gave the impression that they were white rays showing through the bands. The pink coloration gradually spread across the zenith towards the south-east where it appeared as a darker red patch, due to the background not being illuminated. At the same time there appeared a few faint luminous marks to the north-east, again quite close to the zenith. By 1.35 all that remained was a much fainter glow to the north and north-west, and this persisted until 2.30, when I went to bed."

A letter received in the Meteorological Office from Mr. J. M. Brierley, of Rodwell, South Petherton, Somerset, describes the phenomena as seen on a motor-car journey from Honiton to Ilminster. Here a rosy glow was observed in the north-north-west as early as 6.0 o'clock. By 6.30 the glow had increased greatly in size and brilliance, and numerous pale green streamers were observed. Until 8.05 the main features were a general display of rose-coloured light above a greenish arch extending almost from west to east, and reaching almost to the zenith. A period of maximum brilliance occurred at 8.05; the greenish arch was then at an elevation of about 45°, and above this was a rose-coloured arch nearly 90° broad. Numerous bright streamers appeared along the whole greenish arch and converged to a point between Aldeboran and the Pleiades. The green arch persisted until 11 p.m., after which the display was terminated by cloud.

Mr. R. Moss, Wellington College, Berks, has sent us a copy of a detailed record of observations made by two pupils, M. Majendie and J. H. Gordon, at the College, between 6 p.m. and 11.30 p.m. The period of maximum activity and brilliance was noted to have occurred between 7.45 and 8.0 o'clock and a second very active period between 8.30 and 8.45. Observations of the characters and extensions of different parts of the display were made every few minutes, and notes were written down at once, so that the record has far greater value than the general accounts of the display usually regarded as sufficient. A copy of the notes has been sent to the auroral branch of the British Astronomical Association, and Mr. Moss will be pleased to supply further information concerning the observations to anyone especially interested in them.

In a leading article in *The Times* of January 27, reference was made to the belief, going back to the time of Tacitus, that the aurora gives forth sounds. It is of interest to record that an observer at Catcott, Bridgwater, Somerset, the Rev. Harold Buckton, states that he seemed to hear now and again faint clicks resembling the noises made by the sparking of an electric machine. He is positive that these sounds were not caused extraneously, and he was not in fact aware of the possibility of sounds in association with the aurora, until he saw the matter referred to in *The Times*. The modern view is that sound could not reach the earth's surface from an electrical discharge occurring at heights of sixty miles or more, but we include the observation in these notes for what it is worth.

The subject was referred to by Prof. A. S. Eve in a discourse delivered at the Royal Institution on February 7, 1936, and published in a supplement of NATURE of May 16, 1936. Prof. Eve's view is that the aurora can make little or no noise, and that what is heard is of the nature of local brush discharge such as is frequently associated with electrical disturbances. An interesting letter upon the subject appeared in our issue of December 2, 1933, from F. T. Davies and B. W. Currie, of the Canadian Meteorological Office, Toronto.

SOLAR AND TERRESTRIAL RELATIONSHIPS

The great aurora and magnetic storm of January 25 last was a spectacular reminder of a solar-terrestrial relationship, the evidence for which has been slowly accumulated for nearly a hundred years. Although the connexion between magnetic storms and the aurora borealis (or australis) is not a simple one, yet there is in general a close association between the two phenomena. The observation of disturbances in the earth's magnetic field is a fairly straightforward matter, requiring, of course, a specially prepared magnetic observatory, but being independent of the weather. On the other hand, data of the aurora are disturbed by cloudy weather and the periodic occurrence of bright moonlight. As defined at Greenwich, a small magnetic storm is a disturbance in which the range in magnetic declination equals or exceeds $\frac{1}{2}°$ or that in horizontal force or vertical force equals or exceeds 150γ; a great storm is one having double these ranges as minimum (see NATURE of January 29, p. 192).

The evidence for a solar connexion with magnetic storms and associated auroras may be briefly summarized as follows: (1) a general accordance between the frequency curves of sunspots (or some other suitable criterion of solar activity) in the well-known eleven-year cycle and similar curves of magnetic storms. (2) An observed tendency for the lesser magnetic storms to recur at intervals of about twenty-seven days, which is the time taken for the sun (more particularly the mean latitude of the sunspot zones, one north and the other south of the sun's equator) to rotate once on its axis with respect to the earth moving in its orbit around the sun. Auroras likewise show this same recurrence tendency in a period of twenty-seven days. (3) A statistical relationship existing between the occurrence of individual sunspots of great size and the occurrence of great magnetic storms and associated auroral displays. Specific cases of joint coincidences between great sunspots, great magnetic storms, and unusual auroral displays witnessed in the south of England include those of March 22–23, 1920; August 9–10, 1917; November 17, 1882; August 28 and September 2, 1859, the last being associated with the unique observation, made by Carrington and Hodgson, of a transitory bright spot on the sun seen in integrated light with an ordinary telescope. At the commencement of a great magnetic storm, the associated sunspot is found on the average about one day past the sun's central meridian. This asymmetry with respect to the central meridian is thought to be indicative of the time of travel required for the solar agency to travel from the sun to the earth. An informative feature, often shown by great magnetic storms, is their abrupt commencement at the same time (U T.), so far as can be determined at widely separated magnetic observatories.

Apart from these special disturbances in the earth's magnetic field, illustrated by the recent aurora and magnetic storm, mention should be made of the high degree of accordance between curves of some solar index (say, smoothed mean daily areas of sunspots for each month) and curves similarly prepared which give the mean daily ranges of the earth's magnetic elements, *D*, *H* and *V*, after the seasonal inequality has been eliminated. No other known terrestrial phenomenon gives such detailed accordance with the observed periodic curve of solar activity.

To revert to the coincidences shown statistically by individual sunspots of first magnitude and great magnetic storms, it should be noted that as we proceed to the lesser sunspots and lesser magnetic storms, the relationship becomes less and less evident, and one concludes that the solar disturbances primarily related to the magnetic storms and associated auroras do not always produce a visible marking on the sun such as a sunspot. This point is clearly brought out in "time-pattern" diagrams prepared by J. Bartels to show synchronous or nearly synchronous solar activity and magnetic activity on the earth. The occurrence of the recent aurora is also an anomaly. Between January 12 and 24 a very large sunspot crossed the sun's disk. Magnetic storms were recorded in Great Britain commencing on January 16 and 22, and there were reported auroras in Canada. On January 25, when the great auroral display was seen, the big sunspot had been carried out of view by the sun's rotation. A spectroscopic examination of the sun's disk naturally suggests itself, but so far no distinctive phenomena have been reported which could reasonably be associated with the aurora and magnetic storm.

Characteristic features of the aurora itself have been investigated by studying (1) typical forms, (2) geographical distribution (annual and diurnal frequencies), (3) height above the earth's surface, (4) the characteristic spectrum. A useful collection of auroral photographs enabling the observer to identify typical forms is given in a "Photographic Atlas of Auroral Forms" published in 1930 by the International Geodetic and Geophysical Union. As is well known, the zone of maximum auroral frequency roughly circles the earth's magnetic poles in magnetic latitude 67° (the position of the north magnetic pole being in geographical longitude 96° W. and latitude 70½° N., and that of the south magnetic pole in longitude 151½° E., and latitude 71½° S.). Thus for places in the same geographical latitude, Canada is, for instance, more favourably placed for observing polar auroral phenomena than is Great Britain.

The association of magnetic disturbance with the aurora was first remarked by Halley in 1716; but as already noted, the association is not a simple one; auroras have been observed in the absence of marked magnetic disturbance and vice versa. Near the auroral zone itself, the frequency data of auroras fail to show a marked peak corresponding with solar maximum such as is given by the frequency curves of magnetic storms and auroras recorded in lower magnetic latitudes. It has been suggested by Vegard that the generally increased magnetic disturbance near sunspot maximum is instrumental in conveying auroras from the auroral zone to lower latitudes, thus reducing the frequency in the auroral zone itself. This suggestion finds corroboration in the results of a comparison made, by A. Röstad, between the position of auroral displays observed in Trondhjem, Oslo and in Holland and the intensity of the simultaneous magnetic storms recorded at Potsdam. Theoretical and practical investigations by Birkeland and Størmer have shown that if the earth encounters a beam of electrified particles, then the particles will be deflected by the earth's general magnetic field into two zones (to be identified with the auroral zones) one in the northern and the other in the southern hemisphere. The nature of these streams of particles has been the subject of several more recent investigations by Størmer, Chapman, Lindemann, Milne, Vegard, and others. Although the precise nature of the streams is undetermined, it would seem that they must consist of electrified particles of considerable energy so as to penetrate the earth's atmosphere to the lower observed limit of the aurora (about 70 km.). It will be noted that the deflected corpuscles are able to come down on the night side of the earth, the diurnal distribution of the aurora showing a pronounced maximum near midnight, reckoned with respect to the earth's magnetic axis.

The determination of the height of auroras has in recent years been made systematically by measuring the angular displacement of distinctive features of a particular aurora against the background of bright stars, as recorded on two simultaneous photographs taken at opposite ends of a long base line. Eventually it should be possible to decide whether the aurora ever comes down to very low levels as is sometimes reported.

The average height of the lower limit is about 106 km.; there is greater scatter for the upper limit, which shows some dependence upon type and distribution of light intensity along the streamers. The near coincidence in height between the average lower level of the aurora and that of the *E*-layer explored by radio-echo observations would appear to be other than fortuitous.

The spectrum of the aurora long presented great difficulty, and although important advances have been made, knowledge of the origin of the spectrum is by no means complete. In 1925, the well-known prominent auroral green line at 5577 A. (discovered by Angström in 1866) was proved by McLennan and Shrum in their laboratory in Toronto to be due to oxygen in a metastable state. The great intensity of this line is explained by Vegard as being due to oxygen excited to emit this radiation by means of collisions of the second kind with activated nitrogen. Besides the prominent green line, there are two lines in the red, at 6300 A. and 6365 A., both of which are thought to be due to oxygen. In addition, the visual spectrum is characterized by the negative band spectrum of nitrogen. A phenomenon of great interest, studied in particular by Lord Rayleigh, is the light of the night sky, the spectrum of which shows the same green radiation at 5577 A. as does the aurora, although the negative band spectrum of nitrogen is missing. Babcock accurately derived the wavelength as 5577·35 ±0·01 A. It has been suggested by Rayleigh (*Proc. Roy. Soc.*, A., **106**, 135) that the light from the non-polar aurora (as represented by the night sky luminescence found generally distributed over the world) is of a phosphorescent nature, the luminosity being excited by the sun during the daytime and carried round by the earth's rotation. It is important to note the distinction between the non-polar aurora and the polar aurora as exemplified by the recent display.

In conclusion, mention may briefly be made of the work of solar observers in trying to identify the precise phenomenon on the sun responsible for the occurrence of magnetic storms and their associated auroras. Replicas of Dr. Hale's spectrohelioscope, perfected by him in 1926, have been systematically used by a number of observatories in searching for and recording bright chromospheric eruptions which might, it was thought, be related to perturbations in the earth's magnetic field. Although no definite progress can be claimed in obtaining observational evidence of corpuscular streams (the search for which had been urged by Chapman), a new relation has been brought to light in which the solar agency appears to be radiation in the ultra-violet. There is now little doubt that sudden bright chromospheric eruptions (usually near sunspots) visible in $H\alpha$ with the spectrohelioscope or on Ca^+ spectroheliograms produce an immediate (that is, within about the time taken for light to reach the earth from the sun) disturbance in the ionosphere over the sunlit hemisphere, apparently just below the *E*-layer. At the same time, relatively small magnetic perturbations may occur, the effect of which is recorded within a limited distance from the place where the sun is in the zenith at the time of the solar eruption. These small disturbances in the earth's magnetic field are, however, clearly to be distinguished from the magnetic storms and auroras considered above, which are essentially high lattitude phenomena.

Obituary Notices

Prof. W. H. Pickering

PROF. W. H. PICKERING died on January 21 at his home at Mandeville, Jamaica, at the age of seventy-nine years, after several months of failing health. He was a younger brother of E. C. Pickering, the director of the Harvard College Observatory from 1876 until 1920.

Born at Boston in 1858, Pickering graduated at the Massachusetts Institute of Technology in 1879, and became a lecturer there, and at the same time was an assistant professor at the Harvard College Observatory. His first astronomical observations were at the eclipse of 1878, where he observed the radial polarization of the corona. For a time he was in charge of the Harvard College Observatory Station at Arequipa. Vol. 33 of the *Harvard College Annals* contains his researches on the determination of photographic stellar magnitudes, the Great Nebula in Orion and visual observations of the moon and planets.

In 1900 Pickering established the Harvard College Observatory at Mandeville, and while there published a lunar atlas from photographs taken with a 12-inch lens of focal-length 135 ft. The disk of the moon is divided into sixteen parts, and each part photographed under five different illuminations. In 1898 he discovered by photography a small satellite of Saturn at a distance of 8 million miles from the planet and revolving round it in a year and a half. This satellite, to which he gave the name Phœbe, is remarkable in that it revolves in a direction contrary to the other eight satellites, a peculiarity which was later found in three faint satellites of Jupiter.

At Mandeville, Pickering continued his visual observations of the moon and planets. He observed Mars under good climatic conditions and was satisfied of the existence of the "Canals" and drew the more important ones in agreement with Lowell. He regarded them as belts of vegetation of widths up to 150 miles along assumed water courses. In 1921 he challenged the view taken by astronomers that the moon was dead and that no changes took place on its surface in a paper contributed to the Royal Astronomical Society on "Seasonal Changes occurring in certain Lunar Craters". These he attributed to patches of snow which disappeared gradually and reformed. These changes have not been confirmed, and must be attributed to differences of definition.

Pickering, Percival Lowell and George Forbes all made calculations to discover an extra-Neptunian planet. Pickering used the slight deviations of the orbit of Uranus, Lowell and Forbes the slight deviation of the orbit of Neptune (and in the case of Forbes the existence of a so-called family of Neptunian comets), as data for the existence of this body. The position of the planet was found by both Pickering and Lowell from these wholly insufficient data, and strangely enough a planet was found by Tombaugh at the Lowell Observatory on January 21, 1930. Judging from its brightness, the mass of the planet is too small to exercise any appreciable perturbation on Uranus or Neptune.

Prof. Pickering married Anne Atwood, daughter of Mr. Isaac Butts of Boston. They visited England a number of times and made many friends. Prof. Pickering spoke several times at the Royal Astronomical Society, of which he was elected an associate in 1910. He has also addressed the British Astronomical Association, as he was greatly in sympathy with amateur observers. F. W. D.

WE regret to announce the death of Sir James Crichton-Browne, F.R.S., a pioneer in the treatment of mental disease, which occurred on January 31, aged ninety-seven years.

News and Views

Mr. W. M. H. Greaves

THE King has approved, on the recommendation of the Secretary of State for Scotland, the appointment of Mr. W. M. H. Greaves, chief assistant of the Royal Observatory, Greenwich, to be astronomer royal for Scotland and professor of astronomy in the University of Edinburgh, in succession to Prof. R. A. Sampson, who retired recently. Mr. Greaves entered St. John's College, Cambridge, in 1917. He obtained a first class with distinction in Part II of the Mathematical Tripos and was awarded the Tyson Medal for astronomy. He obtained a Smith's Prize in 1921 for an essay on the movement of asteroids of the Trojan group, was awarded an Isaac Newton Studentship and in 1922 was elected a fellow of his College. Mr. Greaves was appointed chief assistant at the Royal Observatory, Greenwich, in 1924. The most important work undertaken by Mr. Greaves at Greenwich has been the development of methods for the determination of the colour temperatures of stars. The observations are divided into two parts: the determination of the relative gradients of the spectral energy curves and the fixing of the zero point of the temperature scale. The determination of the zero point is a long and intricate investigation, requiring reference to a terrestrial source; it has been undertaken twice with concordant results. The mean colour temperature for stars of spectral type $A0$ was found to be 18,000° K.; this value is appreciably higher than had previously been accepted but has since been confirmed by other investigators. Mr. Greaves has also been in charge of the magnetic work at Greenwich and has made some valuable investigations of the relationships between sunspots and magnetic storms. Mr. Greaves was secretary to Section A (Mathematics and Physical Science) of the British Association from 1924 until 1931, and has been secretary of the Royal Astronomical Society since 1932.

Accident to Dr. W. W. Vaughan

MOST of the members of the British Association delegation to the jubilee meeting of the Indian Science Congress Association have now returned, and one of them has kindly told us the circumstances of Dr. W. W. Vaughan's lamentable accident at Agra. It appears that Dr. Vaughan, with Mrs. Vaughan and other members of the delegation, had gone to the Taj Mahal before moonrise on the night of the party's arrival at Agra. In the darkness, he missed his footing on the upper of two terraces between which there is a fall of several feet, without any parapet. He fell on to the lower terrace, and his leg was broken above the knee. Help was obtained from other members of the delegation, and also, very fortunately, from an Indian friend of one of them, who, as a resident in Agra, knew what to do. But there was a weary wait for the sufferer before an ambulance could be got, during which he retained both consciousness and, by all accounts, the bravest bearing. The Thomason Hospital at Agra received him with every attention. It is now known that the leg, which had not been healing satisfactorily, was amputated on Monday, January 24; a private message on the following Thursday spoke of the patient's condition as "improving", and a press bulletin on January 31 appeared equally favourable.

International Economic Collaboration

THE able report by M. Van Zeeland on his mission of inquiry to various countries, directed to "the possibility of obtaining a general reduction of quotas and of other obstacles to international trade", was published in the press on January 28. His proposals in the main are very much in line with views that have been repeatedly expressed in NATURE, and they should receive serious consideration by all Governments. His immediate object is to bring together representatives of the principal economic Powers—in particular, Great Britain, the United States, France, Germany, and Italy—in the hope that they may succeed in working out an agreed plan of international economic collaboration. That there is ground for this hope is clear from the fact that everywhere he went M. Van Zeeland tells us that he met with a most sympathetic reception. The report he has so carefully prepared should provide an excellent basis for discussion. It is well balanced, stating frankly the difficulties which have to be faced without being too caustically critical of the narrow nationalistic aims recently pursued by nearly all countries.

AMONG the more fundamental problems for which a solution must be found, two in particular have received a good deal of advertisement, different countries advocating claims and counter-claims in regard to them, namely, those which relate to raw materials and colonies. It is highly important that such problems should be approached, as M. Van Zeeland urges in his report, "in a spirit of complete objectivity". That is a sound principle which every man of science will be ready to endorse. As to colonies, the most promising line of attack seems to be, again quoting the words of the report, "to seek for the means of generalizing the system of the open door which obtains in the Conventional Basin of the Congo, a system the general result of which it is impossible to criticize". So long as colonial Powers are in a position to exercise monopoly rights in the areas they control, dissatisfaction is bound to remain in the minds of those ruling the nations that are shut out, and such dissatisfaction is the potential seed of war.

Niagara Falls Bridge Disaster

THE well-known Niagara Falls View Bridge across the Niagara River, just below the falls, a steel-framed structure in a single span of about 1,200 feet, weighing some 2,600 tons and erected in 1898 at a cost of £60,000, collapsed during the afternoon of January 27, under the pressure exerted by an enormous mass of pack ice which had accumulated at the foot of the Falls. By reason of the intense cold of the preceding weeks, the ice had piled itself in huge blocks as it was swept over the Falls, to a height not much less than the deck level of the bridge, which was 165 feet above the river, and the danger had been clearly recognized for some time previously, so that when, despite the efforts made to save the bridge with heavy timber fenders, the final collapse took place, the sight was witnessed by a crowd estimated at ten thousand. The broken bridge now rests in a tangle of twisted steelwork upon the surface of the ice, which continues to gather and fills the gorge for a distance of two or three miles. There is another bridge for rail and road traffic about a mile and a half downstream, and this will have to be utilized for pedestrians until the fallen bridge is replaced. The drift of ice towards Lake Ontario is causing concern lest damage should be done to the generating station and plant of the Ontario Hydro-electric Commission, which is a short distance below the Falls. As it is, there is serious interference with the supply of electricity due to the fracture of mains.

Decibels and Phons

A CORRESPONDENT has raised the question of the use of the decibel as a unit for expressing sound intensity. Since his difficulties are shared by others, it seemed worth while to place them before an authority on the subject, who has been good enough to deal with them. He points out that it is not always realized that the decibel is a unit for specifying changes in intensity, power, or energy, and not a direct measure of the absolute value of these quantities. Decibels are not additive, since they measure changes on a logarithmic scale; so that it is the ratio of two sound intensities which determines their difference in decibels. Two similar sounds of intensities I and I_0 are said to differ in intensity by n decibels when $n = 10 \log_{10} I/I_0$. Hence a 10-fold increase in the intensity of a sound is a 10 decibel change, a 100-fold increase a 20 decibel change, and a 1000-fold increase a 30 decibel change. A decibel corresponds to an increase of intensity or energy in a ratio of approximately 5/4, two decibels to a ratio of $(5/4)^2$, three to a ratio of $(5/4)^3 = 2$, . . . and so on. Thus doubling the intensity of a sound, as when two similar voices sing the same note, corresponds to a change of 3 decibels. When a sound is said to have an intensity of so many decibels, it is implied that the intensity is being compared with some intensity which has been selected as a zero level. An international conference held in Paris last July adopted an intensity corresponding to an acoustical pressure of 0·0002 dyne per sq. cm. as the reference zero, this being near the threshold of hearing for sounds with frequencies in the neighbourhood of 1000 cycles per second.

IT will be seen that the decibel is a purely physical unit and is independent of the characteristics of the ear, which assesses loudness and not intensity. Moreover, two sounds of the same intensity but of different quality will not necessarily appear to be equally loud. For comparing the loudness of sounds, a scale of phons has been set up, based upon the fact that individuals find it possible to judge whether sounds of differing quality produce a sensation of equal loudness. Any sound or noise is matched under specified conditions against a pure reference tone with a frequency of 1000 cycles per second. If the intensity of the reference tone in decibels above the zero level is n, the reference tone and the sound or noise are said to have an equivalent loudness of n phons. For sounds of medium frequency and moderate loudness, a phon happens to correspond roughly to the smallest difference of loudness which can be detected by alternate listening under ordinary conditions.

Educational Science at Cambridge

THE recommendations of the Special Syndicate at the University of Cambridge on the position of the

University Training College for Schoolmasters are of far-reaching importance and, if carried into effect, may have great influence on the development of educational methods. The Syndicate recommends the creation of a professorship of education and the establishment of a Department of Education in the University. The last Royal Commission on the University recommended that such a professorship should be founded, and the Syndicate advances cogent reasons why it is particularly opportune for the chair to be founded at the present time. The systematic study of educational problems, especially in so far as psychology bears on these, has advanced in no uncertain manner during recent years, and it is vitally important for the University to be intimately concerned with these developments; only thereby can it exercise due weight in the educational progress of the nation. To obtain a person of sufficient initiative, experience and prestige, the Syndicate considers that the head of the Department of Education should have the status of professor, as is the case in certain other universities.

£750,000 Claim against the University of Oxford

IN Congregation at Oxford on February 1 the Vice-Chancellor announced that the claim of the company which has been suing the University for £750,000, following the conviction of B. J. Owen, formerly director of the Institute for Research in Agricultural Engineering, had been settled by a payment by the University of £70,000. This ends satisfactorily, it may be said, a trouble that has been threatening the University off and on during the past seven years. It began in 1926, when the director of the Institute for Research in Agricultural Engineering sold to the plaintiff company patents relating to the extraction of sugar from beet which were stated to be novel and excellent but which proved to be worthless. The company believed that the director was acting throughout as agent of the University and that the representations he made in that capacity resulted in the loss by the company of much of its capital. The necessity for this large payment is, of course, a serious blow to the University, but the money required will not be diverted from any of the funds for which appeals have been made in recent months.

The British Film Institute

THE British Film Institute has recently published its fourth annual report (1937). It is an interesting record of rapid development and growing usefulness. It is clear that the exploratory phase in the use of the film in education has passed and that the time has come to put into effect the lessons learnt. But it is disappointing to learn that a census recently carried out by the Institute showed that only 916 projectors are available in the educational institutions of Great Britain. This is fewer than one tenth of the number in use in the United States, Germany, France, Italy, etc. Both the Board of Education and the local education authorities are concerned at this slow progress, and are doing their best to encourage teachers to make more use of visual material. The Board of Education is now willing to pay 50 per cent of the cost of any projectors installed. Among the numerous publications sponsored by the Institute in 1937, one is of special interest to teachers of science—the report prepared by the Science Panel. This contained, besides advice on technique of use, etc., a list of 455 science teaching films. Two thirds of these are concerned with biology—a subject well suited to visual presentation. It is unfortunate that so few films on physics and chemistry are available.

THE British Film Institute records that it is watching with close attention the work being done by the new cinematograph group of the British Standards Institution. This group is devising simple methods of testing the effective light output of projectors and is framing regulations for the use of non-flam films. The National Film Library, which now contains 268 films, is growing very slowly—shortage of funds is a great handicap. Recently the Library received a valuable gift from the Paisley Philosophical Society: a collection of films exhibited in 1901, which had been put away and apparently forgotten. These films are still in good condition though they need refixing and rewashing. It is interesting to note that the use of films in education is growing rapidly in other parts of the Empire: Canada has set up a National Film Society, the Minister of Education of South Africa has founded a Film Division, in East Africa a film library is to be set up, at Achimota College (Gold Coast) a library has been started. In all these cases, the co-operation of the Film Institute has been secured.

London School of Hygiene and Tropical Medicine

IN the report on the work of the London School of Hygiene and Tropical Medicine for the year 1936–37, the Board of Management notes that Mr. Neville Chamberlain has accepted the chairmanship of the Court of Governors vacant through the death of Sir Austen Chamberlain. The Dean of the School, Prof. W. Jameson, reviews the teaching and research work of the various departments. A course on mental deficiency, designed to enable medical practitioners to secure recognition by the Board of Education as certifying officers under the Mental Deficiency Acts so far as elementary school children are concerned, was held in the School for the first time in February, and proved an unqualified success, all available places being filled. Dr. Hamilton Fairley and Mr. R. J. Bromfield spent six weeks in Macedonia studying blackwater fever, and confirmed the presence of a new pigment, 'pseudo-methæmoglobin', in the blood in that disease. In the Department of Entomology investigations have been pursued into the production of satisfactory anti-larval oils for the destruction of mosquito larvæ in malaria control, and on the biology of the bed-bug. Sir Malcolm Watson contributes the report of the Ross Institute of Tropical Medicine, now incorporated in the School. He directs attention to the importance of agriculture in the tropics and of teaching health officers practising there the principles of farming. Workers abroad are largely concerned with the prevention of malaria, and in Northern Rhodesia they had been able to reduce the mortality from this disease among the European workers in the copper mines from 22 to 9, and among the natives from 31 to 5, per 1,000.

Meteorological Service for Indian Air Routes

"METEOROLOGICAL ORGANISATION FOR AIRMEN, 1937", is the title of a pamphlet compiled under the direction of Dr. C. W. B. Normand, Director-General of Observatories, India Meteorological Department, for the benefit of airmen flying anywhere between the Persian Gulf and Burma (Delhi: Manager of Publications. 2*s.* 3*d.*). It describes the organization maintained by the India Meteorological Department on behalf of aviation, the nature of the information about current weather that is obtainable from that organization, and all that an airman requires to obtain that part of the information which he may require on any flight. Full information in regard to the latter must include the addresses and telephone numbers of officers responsible under the Director-General for particular parts of the whole area dealt with, their office hours, and the times at which they complete synoptic weather charts, if the airman is to make the most of the information available. It may be noted, however, that on the trans-India air route between Karachi and Victoria Point, Burma, the issue of different kinds of meteorological message by wireless to all the main aerodromes has been organized on a routine basis and the latest information can be obtained from weather notice boards at such aerodromes; alternatively, it can be obtained by the airman by wireless while he is in flight. All these points are systematically treated in a series of tables that occupy most of the pamphlet, and among these tables are the very important ones that explain the different codes which make it possible to condense much information about actual and expected weather into telegrams or wireless messages. There is a key map showing the positions of the various types of meteorological station, and the boundaries of the different forecast areas and provinces. The organization embraces the whole of Baluchistan and Burma as well as India.

Royal Scottish Society of Arts

THE Royal Scottish Society of Arts is, like its prototype the Royal Society of Arts, one of the few unspecialized learned societies. It draws together men engaged in the pursuit of applied science and art of the most diverse kinds. In a prospectus just issued, this peculiarity is emphasized, and it will doubtless be accounted to the Society for righteousness by those who set a high value on general culture. The principal objects of the founders were "to stimulate and reward genius and mechanical industry and to afford a ready and useful medium of intercourse among men of all ranks who were engaged either in the pursuit of Science or in the various practical departments of the Arts and Manufactures". During the winter session there are fortnightly meetings at which papers are read, and a course of special lectures on a subject of general interest is given by a selected specialist. Prizes are offered for inventions and communications. The Council desires to suggest, especially to prospective student members (for whom the annual subscription is only 5*s.* up to the age of twenty-three years) that attendance at the ordinary meetings and participation in discussions provides an extremely easy and really valuable means of extending their general and technical education. Evidently a complete survey of adult education would not ignore the opportunities offered by this Society.

Modern Sylviculture

IN an article entitled "Revue de Sylviculture", published originally in the *Revue generale des Sciences pures et appliquees* (48, No. 7, April), Prof. H. Perrin deals with the practice of modern sylviculture more especially from the French point of view. He points out that in former times the forest was regarded solely as a source of supply of timber and smaller materials, on the supposition that such supplies would continue inexhaustible. Latterly, he says, there has been a swing-back, in some quarters, to this point of view. He pleads for a return to, or a continuance of faith in, the sylvicultural principles laid down by the old masters of the science or art, of whom the last century provided some of the best known. Perrin deals with the various aspects of, and factors influencing, sylvicultural practice, and details in a general manner French methods. A close acquaintance with the forest is not easy to acquire, owing to the fact that the methods of investigation common to all the biological sciences are difficult of application in the forest; long years of observation must be passed during which generations of men succeed each other; and only continuity and persistence will result in that sylvicultural knowledge and practice which is the antithesis of the 'get rich quick' theory as applied to forest management, which has made its appearance of late years in places.

The R.H.S. Lily Year-Book

CONTRIBUTIONS from the point of view of the practical gardener predominate in the Royal Horticultural Society's Lily Year-Book for 1937 (from the Society's Office, Vincent Square, Westminster, S.W.1, 5*s.* paper; 6*s.* cloth; pp. 153. Oct. 1937). Information upon the choice of lilies for all situations in the garden can be found in it, and the increasing popularity of *Nomocharis* and fritillary is reflected by several articles on these genera. Dr. W. B. Turrill contributes a useful taxonomic study on fritillaries, giving detailed descriptions of anatomy. A report of discussions upon the propagation of lilies from scales provides much practical information. Two papers, by Dr. Fred Stoker and F. C. Stern, compare lilies which will grow on lime-free and lime soil respectively. No sharp distinction can be drawn between the lily flora of these two horticultural habitats, and the absence of more scientific experiments leaves a doubt as to whether lime or some other influence is really the controlling factor. Mr. L.

Ogilvie describes experiments upon the depth of planting, and the effects of high and low temperatures, on lily bulbs. One cannot escape the conclusion, however, on considering the contents of the present volume, that it deals with less fundamental questions than previous issues.

Leeds College of Technology

ON the occasion of the distribution of prizes and certificates by Sir William Bragg on December 7, the principal of the Leeds College of Technology presented a report on the work of the last session, emphasizing the value to the local industries of the thoroughly up-to-date technical instruction given in the College to more than three thousand of their personnel. The total number of students was 3,862, of whom 3,320 attended evening classes only and 375 attended part-time day and evening classes. Although education authorities are often inclined to disparage evening classes on the ground that after a hard day's work people cannot be expected to be fit for serious study, they are nevertheless a very valuable part of the country's educational resources. As the principal points out, they are, moreover, capable of exerting a definitely beneficial effect on character: "To attend evening classes regularly after the day's work, for several sessions, each of which includes an English winter, is an indication of grit and perseverance in addition to intellectual ability". It is noteworthy that 379 students were released by employers to attend part-time day classes, generally in addition to evening classes.

Vocational Guidance

A 'VOCATIONAL GUIDANCE' pamphlet has been issued by the University College of the South-West of England, Exeter, for the use of parents and others. It gives a list of the various college courses with particulars of their duration and the fees payable for them, a list of vocations (other than teaching) for which the courses offer suitable preparation, and a list of other vocations. The attention of parents is directed to the fact that in some cases the course of study is of one year's duration only and entails no long or expensive training. Accompanying the pamphlet is a leaflet directing attention to the increased demand for scientific investigators both for routine and research duties, to the importance for entry into commerce or industry of good qualifications in modern languages and economics, and to a new course for a diploma in public administration. This diploma will, it is anticipated, be a valuable qualification for higher posts in the national and local government services.

The Laxminarayan Technical Institute, Nagpur

THE foundation stone of the Laxminarayan Technological Institute was laid by His Excellency Sir Hyde Clarendon Gowan, Chancellor of the Nagpur University, at Nagpur on December 8, 1937. The Chancellor paid great tribute to the untiring efforts of the present Vice-Chancellor, Sir Hari Singh Gour, in acquiring the present site for the Institute, which will be surrounded by charming scenery. The construction of the Laxminarayan Technological Institute and its workshop is the result of a princely bequest, now amounting to more than £400,000, made by the late Rao Bahadur D. Laxminarayan in 1930 to the University of Nagpur for the teaching of applied science and chemistry. The University has decided to begin with the creation of a department of applied chemistry for teaching and research work in this subject. Dr. R. S. Thakur, who had been deputed for the last two years by the University of Nagpur to visit England and the continent of Europe for practical training in applied chemistry, with special reference to oil technology, has now been appointed as the organizing officer. It is expected that the Institute will be in active operation about July of next year.

Refrigeration Conference

A REFRIGERATION Conference will be held in London on July 12, in the rooms of the Royal Society. This Conference, which is convened by the British Association of Refrigeration, will take place immediately following a meeting at the same centre of the Technical Commissions of the International Institute of Refrigeration, an organization with headquarters in Paris. The subjects provisionally set down for discussion at the Conference, which will be open to all technicians interested in refrigeration, are: influence of low temperatures on enzymes, vitamins, etc.; limitations of 'gas storage'; air conditioning problems; an international unit of refrigeration; standard tables giving the properties of refrigerants. Further information can be obtained from the Hon. Secretary, British Association of Refrigeration, Empire House, St. Martin's-le-Grand, London, E.C.1.

Mathematical Colloquium at St. Andrews.

A MATHEMATICAL colloquium, similar to the very successful gatherings held in 1926, 1930 and 1934, will be held in St. Andrews on July 4–July 15, 1938, under the auspices of the Edinburgh Mathematical Society. Short courses of lectures will be given by prominent mathematicians, including Prof. E. T. Whittaker, Prof. G. D. Birkhoff, Dr. A. C. Aitken, on topics of pure and applied mathematics. On their way to the colloquium, members will have the opportunity of attending a meeting of the Royal Society of Edinburgh, celebrating the three hundredth anniversary of the birth of James Gregory, who held in succession the chairs of mathematics in the Universities of St. Andrews and Edinburgh. This meeting will be held in Edinburgh on July 4. Further particulars of membership of the colloquium can be obtained from the Hon. Secretary, Edinburgh Mathematical Society, 16 Chambers Street, Edinburgh 1.

The Night Sky in February

FULL moon occurs on February 14 at $17 \cdot 2^h$ and new moon on March 2 at $5 \cdot 7^h$ U.T. No occultation of stars brighter than magnitude $5\frac{1}{2}$ occurs this month.

The moon is in conjunction with Saturn on February 4 at 18^h and three hours later with Mars, the two conjunctions illustrating very well the moon's movement in its orbit around the earth. Mars was in conjunction with Saturn on February 2 at 20^h, and the former continues to move eastwards relative to the latter. Those observers interested in the phenomena of Saturn's satellites should consult p. 30 of the B.A.A. Handbook for the times of eclipses, occultations and transits. The apparent diameter of the minor axis of the ring system is slowly increasing up to a maximum of 8″ in August next. Uranus (6th magnitude) is not far from 29 Arietis, a star of similar magnitude. Neptune is in Leo, and at the end of February is about half-way between 89 Leonis and σ Leonis; the disk presented by the planet is 2½″ in diameter. The well-known eclipsing binary, Algol (β Persei), is becoming less favourably placed for observation. The change in brightness (in 5 hours the star loses two-thirds of its light and then returns to its original brightness in the following 5 hours) can be seen best about 1½ hours before and after the following epochs: February 6^d $23{\cdot}8^h$; 9^d $20{\cdot}6^h$; 12^d $17{\cdot}4^h$; 24^d $4{\cdot}7^h$, 27^d $1{\cdot}6^h$ and March 1^d $22{\cdot}4^h$. In view of the occurrence of magnetic storms commencing on January 16, 22 and 25 (the latter being associated with the great auroral display), it may be worth while watching the northern skies 27 days after each of these dates, especially on or about February 21, when the moon will be absent until after midnight. Analysis of data shows, however, that great magnetic disturbances recorded in this country are much less likely to recur after one synodic solar rotation than those of lesser intensity.

Announcements

THE King of the Belgians has conferred upon Prof. H. S. Taylor, professor of physical chemistry in Princeton University, the Cross of Commander of the Order of Leopold II in recognition of the services rendered by him to Belgium as occupant of the Francqui chair at Louvain in chemistry from January until June of last year.

PROF. A. B. WASICKY, professor of pharmacognosy in the Pharmaceutical Institute of the University of Vienna, was awarded the Hanbury Medal for 1937 of the Pharmaceutical Society of Great Britain and the medal will be presented to him on February 8, when he will deliver a lecture entitled "Modern Points of View and Methods in Pharmacognosy".

MISS JEAN BATTEN has been awarded the Gold Medal of the International Aeronautical Federation. The award was made for the greatest flying achievement of 1937. There were twenty-two nations represented at the Federation's conference, at which the Royal Aero Club represented Great Britain.

THE prize of £100, founded by Viscount Cecil of Chelwood, which is offered yearly for an essay on some subject connected with the maintenance of international peace, and is open to all students, without distinction of sex or nationality, of any university or university college in Great Britain or Northern Ireland, has been divided between Miss Ursula Wasserman of the University of London and Mr. D. D. Hindley-Smith of the University of Cambridge. The subject for the year 1937 was "The Causes of the Failure of the Disarmament Conference".

THE ARCHBISHOP OF YORK (Dr. William Temple) has accepted an invitation to act as president of the Society for the Protection of Science and Learning, formerly the Academic Assistance Council, in succession to the late Lord Rutherford.

PROF. N. V. SIDGWICK will deliver the distinguished visitor's address of the Chemical Society of Birkbeck College, on February 14, at 6 p.m. The title of Prof. Sidgwick's address is "Multiple Links". Admission is free, without ticket.

DR. NANNA SVARTZ-MALMBERG, who is well known for her work on intestinal bacteria and their influence on rheumatic diseases, has been appointed professor of medicine at the Stockholm Caroline Institute by the Swedish Government. This is the first time that a Swedish woman has been appointed professor.

A DISCUSSION on the Ministry of Health new model building by-laws will take place at the Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.1, on February 8 at 5.30 p.m.

AN international conference of teachers to discuss the actual problems of international relations to-day and to exchange ideas and experiences on the methods of teaching international relations and of promoting international friendship and understanding in the colleges and schools will be held in London on April 22–25. Further information can be obtained from the Secretary, Education Committee, League of Nations Union, 15 Grosvenor Crescent, London, S.W.1.

THE Department of Mines and Resources, Mines and Geology Branch, National Museum of Canada, has available a number of reports comprised in a series dealing with the Canadian Arctic Expedition, 1913–18. Many of the publications include half-tone illustrations and maps, and copies will be supplied without charge on application to F. C. C. Lynch, National Museum of Canada, Ottawa, from whom a list of the publications available can be obtained.

ERRATUM. In the letter entitled "Westward Extension of the Ranikot Sea" (NATURE, Jan. 29, p. 202) by Lieut.-Colonel L. M. Davies, the names of species appearing in lines 5 and 6 of paragraph 2 should read as follows: *Operculinoides* cf. *sindensis* (Davies), *Miscellanea stampi* (Davies), *M. miscella* (D'Arch. and Haime).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 250.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Light Scattering and Fluid Viscosity

ACCORDING to well-known hydrodynamical theory[1], plane waves of sound propagated through a viscous liquid suffer a diminution of amplitude in the ratio $1/e$ in traversing a number of wave-lengths given by the quantity $3C\lambda/8\pi^2\nu$, where C is the velocity of sound, λ is the wave-length of sound and ν is the kinematic viscosity. Taking $\lambda = 4358$ A., this number for various common liquids which are fairly mobile at room temperature ranges from about 3 in the case of butyl alcohol to about 30 in the case of carbon disulphide. For phenol at 25° C., the number is less than 1, and for glycerine, it is a small fraction of unity. A consideration of these numbers shows that the theories due to Einstein[2] and L. Brillouin[3], which regard the diffusion of light occurring in liquids as due to the reflection of light by regular and infinitely extended trains of sound-waves present in them, can only possess partial validity for ordinary liquids, and must break down completely in the case of very viscous ones. In an earlier note in NATURE[4], we reported studies of the Fabry-Perot patterns of scattered light with a series of liquids, which showed clearly that the Doppler-shifted components in the spectrum of scattered light fell off in intensity relatively to the undisplaced components, with increasing viscosity of the liquid.

We have now to report some further results which illustrate in a striking way the part played by fluid viscosity in the diffusion of light by liquids. As mentioned in our previous note, the light scattered by liquid phenol at ordinary temperatures gives a Fabry-Perot pattern which is scarcely distinguishable from that of the incident light. When, however, the temperature of the liquid is raised, the viscosity falls off rapidly, and the number $3C\lambda/8\pi^2\nu$ assumes a value which is many times greater than at room temperature. Simultaneously, as can be seen from Fig. 1, the character of the Fabry-Perot pattern alters, and the Doppler-shifted components come increasingly into evidence; at 70° C. they are just as prominent as in ordinary inviscid liquids. The influence of temperature revealed by these studies for the case of the very viscous phenol is to be clearly distinguished from the broadening of the Doppler components with rise of temperature reported by us in an earlier note[5] for the case of carbon tetrachloride.

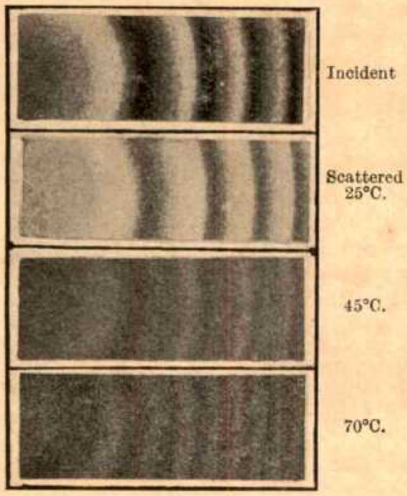


Fig. 1.
INFLUENCE OF TEMPERATURE ON THE SCATTERING BY PHENOL.

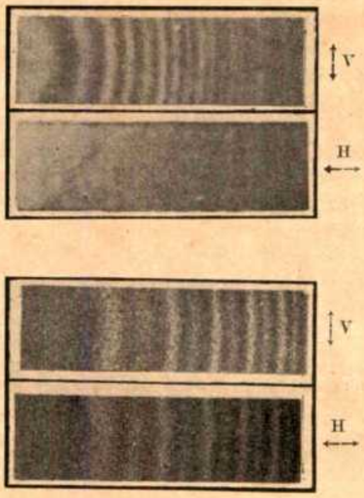

Fig. 2.
STATE OF POLARIZATION; ABOVE, TOLUENE; BELOW, PHENOL.

The four patterns reproduced in Fig. 2 show the remarkable difference in the state of polarization of the Fabry-Perot patterns of transversely scattered light for an inviscid liquid such as toluene and a viscous one such as phenol at room temperature. In the former case, only a continuous radiation is to be observed in the horizontal component; in other words, both the displaced and the undisplaced components in the pattern are sensibly completely polarized with the vibrations vertical. In the case of phenol, however, the undisplaced radiation is evidently partially polarized, as it appears both in the vertical and the horizontal vibrations ; a partial polarization of the continuous radiation is also noticeable.

New Phenomena Connected with Heat Flow in Helium II

SINCE publishing the preliminary measurements on thermal conduction in liquid helium II[1] which showed a variation of conductivity with temperature gradient, further data have been collected concerning the phenomenon.

It was noted that the conductivity appeared to increase as the bore of the conduction capillary decreased. It was then found that at very low temperatures (1·08° K.) small heat flows produced a rise in the level of the liquid in the closed bulb at the heated end of the capillary, instead of the fall caused by increased vapour pressure which was observed for higher heat flows. The apparatus was modified (Fig. 1) so that the top of the bulb at the hot end of the capillary was open to the vapour above the surface of the liquid helium bath. There was thus no possibility of a difference in vapour pressure between the liquid at either end of the capillary. As in the previous cases, heat was introduced electrically by means of a coil inside the bulb. On heating, the level of the liquid again rose in the bulb. The rise in level increased with increasing heat flow, and for constant heat flow increased with decreasing temperature. This effect opposes the effect of increased vapour pressure in the closed bulb, and thus will probably explain the apparent non-linear variation of heat flow with temperature gradient. More complete data on this phenomenon will be published later by one of us (J. F. A.).

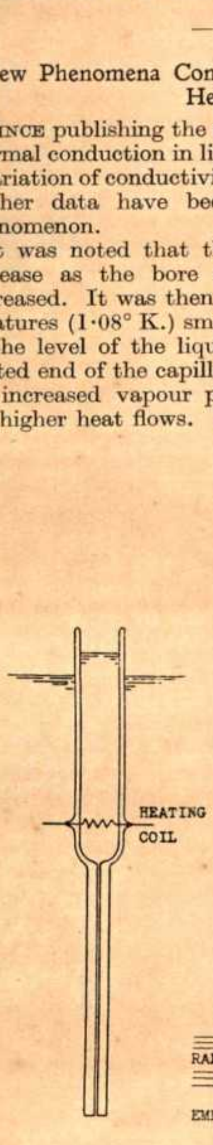

Fig. 1.

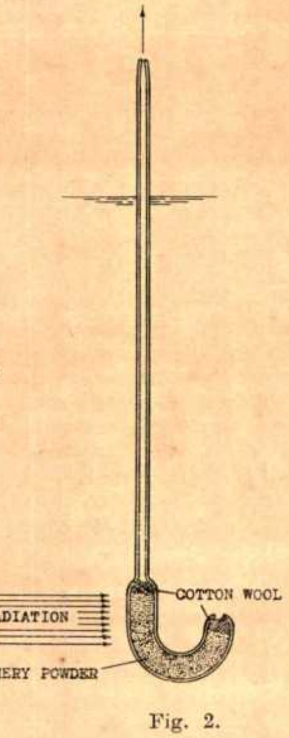

Fig. 2.

A more striking manifestation of the above effect was observed by one of us (J. F. A.) in collaboration with A. D. Misener. Observations were being made on the flow of liquid helium II through a tube packed with fine emery powder (Fig. 2). The top of the tube was allowed to project several centimetres above the level of the liquid helium bath, and an electric pocket torch was flashed on the lower part of the tube containing the powder. A steady stream of liquid helium was observed to flow out of the top of the tube as long as the powder was irradiated.

The principle is the same as that for the thermal conductivity apparatus, in which heat is introduced electrically and flows through a capillary. Here the capillary is replaced by the minute interstices in the powder, and the heat input is obtained by means of the absorption of radiation by the powder particles. The apparatus forms, in effect, a very simple and efficient helium pump. The height of the jet becomes greater for lower bath temperatures and for powder particles of smaller size. A photograph of the liquid helium pump is shown in Fig. 3. The stream rises approximately 4 cm. above the jet, the top of the stream striking the side wall of the flask. The illumination for the photograph consisted of a 60-watt bulb, which also provided the radiant thermal energy for operating the helium pump. The maximum height of jet produced was 16 cm.

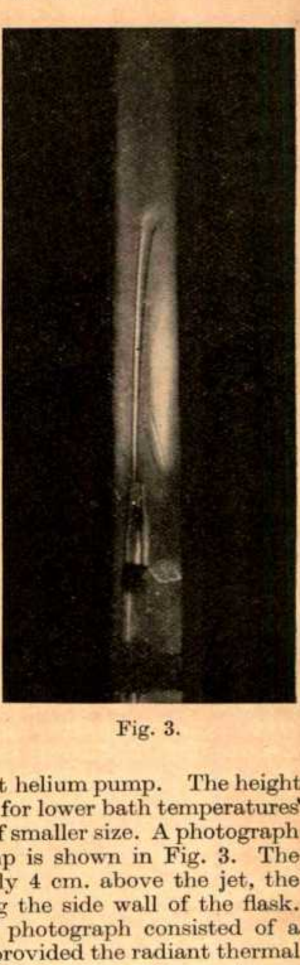

Fig. 3.

The significance of these results may perhaps be understood in the following manner. The observed specific heat of helium II shows that some co-operative phenomenon is concerned. According to Fröhlich[2], this is a disordering process analogous to that occurring in β-brass. Helium II is exceptional, however, in that almost the whole of the thermal energy at the λ-point is energy of disorder. We are led, therefore, to consider heat conduction as a flow of disorder rather than as a flow of vibrational energy. According to a suggestion of London's[3], the ordered state forms a diamond lattice which may be regarded as a body-centred cubic lattice in which only half the lattice points are occupied. According to Fröhlich, the disorder arises when some atoms fill the unoccupied sites of this underlying body-centred structure. Such 'wrong' atoms would be able to jump from one possible site to the next. This model, admittedly naïve, contains an interesting feature, namely, that as the flow of disorder is weakened by collisions with the walls of the containing tube, momentum in the direction of flow is lost. This should be contrasted with conduction by vibrational waves which do not carry momentum. The reaction due to loss of momentum gives rise to a pressure in the opposite direction to the heat flow.

This process of conduction by flow of disorder has been considered in rather more detail by one of us (H. J., to appear elsewhere), and a second process by which a flow of disorder can be dissipated, namely, by interactions with vibrational waves, has been discussed. This latter process will not, of course, result in a 'back pressure'. This pressure will therefore be greater the greater the part played by the walls in the heat resistance. Lessening the bore of the tube in which heat flows, or filling with powder, increases, therefore, for a given heat flow, the magnitude of the back pressure.

Memories of Rutherford in Manchester

When I look back on the five years which I spent with Rutherford as a young physicist in Manchester, many delightful impressions spring to my mind. I see his quiet research room at the top of the physics building, under the roof, where his radium was kept, and in which so much well-known work on the emanation was carried out. But I also see the gloomy cellar in which he had fitted up his delicate apparatus for the study of the α-rays. Rutherford loved this room. One went down two steps and then heard from the darkness Rutherford's voice, reminding one that a hot-pipe crossed the room at head-level, and that one had to step over two water-pipes. Then, finally, in the feeble light, one saw the great man himself seated at his apparatus, and straightway he would recount in his own inimitable way the progress of his experiments, and point out the difficulties that had to be overcome.

There was also a cheerful room upstairs, in which we all met for a cup of tea in the late afternoon. It was perhaps Rutherford's greatest gift to his young pupils and collaborators that he attended with such regularity this pleasant break in the daily routine. Here he would discuss in his lively manner old and new problems in physics, or help us in our experimental difficulties and give us renewed confidence, and here, to the delight of all present, he would so often relate details of his latest successes and discoveries. He might even take us along to his research laboratory and demonstrate to us something that he had himself seen for the first time that very day.

Rutherford always gave most willingly from his rich treasure-house of knowledge, at the same time never thinking of himself. I will mention one instance of this, which is still fresh in my memory. A young physicist who had just arrived in the laboratory commenced work on his research, and before long he was confronted by difficulties. Rutherford suggested to him a new line of attack, which would lead him in a simple and certain manner to a successful termination of his work. But the young man had not quite rightly grasped the significance of Rutherford's suggestions. From that moment, however, what he had heard continued to work on his subconscious self, and he understood gradually the trend of the proposals Rutherford had laid before him. When he saw quite clearly his new plan of action he was delighted, and immediately told Rutherford about these ideas, which he was convinced were his own. But Rutherford only smiled, and congratulated him in words of friendly encouragement on his new plan of work.

I always like to recall another little episode, which occurred at the time when much work was being done in the laboratory with sources of radiation consisting of extremely thin glass tubes filled with emanation. It was necessary to exercise great care lest any of this emanation should escape, for it spread rapidly throughout the building, and by virtue of its activity made experimental work an impossibility for periods of many hours. In his typically drastic manner, Rutherford had threatened the severest penalties for offenders in this matter. One day I noticed that it had become impossible to use an electroscope in my room, where I had fitted up the first counting experiments for Rutherford, and before long other research workers emerged from the neighbouring rooms with the same sad story. We were not long in discovering that the emanation had come from Rutherford's own laboratory, where at that moment he was actively engaged with his experiments. As luck would have it, he came into my room shortly afterwards, and inquired how my work was proceeding. He would have been glad to hear of new developments, but I was brief and to the point. I told him that once again it was futile to attempt to do any work, for the whole building was full of emanation, all of which came from his room. Rutherford looked surprised, and replied: "Well, there you have further proof of the power inherent in this emanation." With this remark he left me; but he soon returned, suggesting that I must be somewhat upset, and that I needed a little fresh air. He took me forthwith in his car for a ride beyond the turmoil of the city, and he was soon discoursing on his own experiments and on all the problems that were yet to be solved. Nothing was so refreshing nor so inspiring as to spend an hour in this way, alone with Rutherford. In spite of the minor provocation, I would be loth to part with the memory of such a day, spent in fellowship with a master-mind.

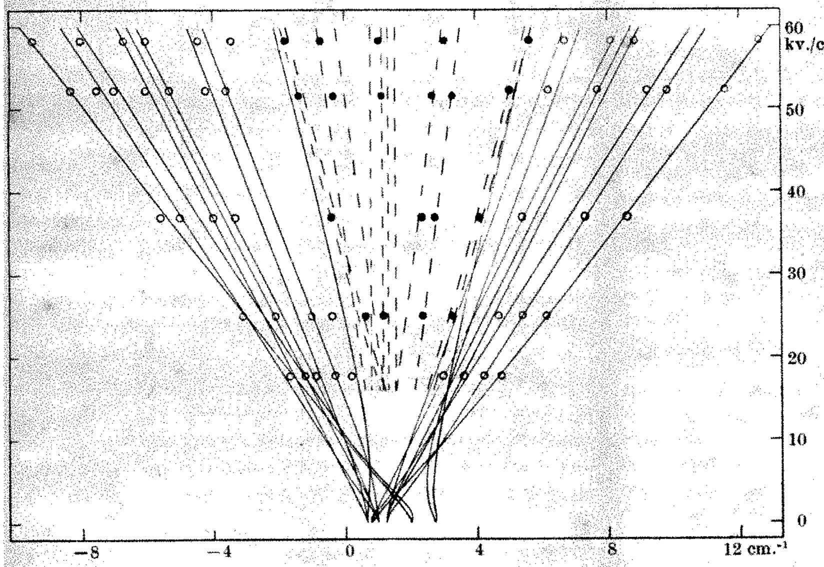
Relativistic Stark Effect of Ionized Helium

The problem of the relativistic Stark effect of hydrogen has been investigated mainly theoretically, the experimental investigation being hampered by great difficulties. These being less pronounced for the lines of ionized helium than for the hydrogen lines, I attacked the problem in question using the He^+ line λ 4686 A. This needed a stigmatic spectral apparatus of high resolving power coupled with great brilliancy. A suitable large autocollimation glass spectrograph with two compound prisms was available, the total base-length of the flint prisms being 30 cm., and the focal length 150 cm. The dispersion in this region is about 2·5 A. per mm. As light source, I used a Lo Surdo tube as modified by Ryde.

Using the standard theory of the relativistic Stark effect of hydrogen, as worked out by Schlapp[1], I have calculated for the above line the displacements and relative intensities of the fine-structure lines for electric fields ranging from 0 to 100,000 v. per cm. The accompanying diagram is intended to give an idea of the theoretical displacements, the extensive numerical data being reserved for a detailed publication. Only those lines have been plotted the calculated intensities of which make them likely to appear on the plates. The theory shows that, in strong fields, most of the Stark components consist of several fine-structure lines the mutual distances of which, apart from the second order effect, do not vary with the field. In weak and intermediate fields, that is, before the groups of fine-structure lines that constitute the ordinary Stark components have become separated, say, below 40,000 v. per cm., the theory draws a rather complicated picture that differs greatly from the symmetrical appearance of the ordinary hydrogen pattern.



STARK EFFECT OF THE HE+ LINE, λ 4686A. FULL LINES CORRESPOND TO p-COMPONENTS, BROKEN LINES TO s-COMPONENTS.

It has been possible to observe a number of fine-structure lines, or groups of such lines overlapping each other, in different fields ranging from 0 to 100,000 v. per cm. If the field is not very weak, the measurements are in good agreement with theory, as will be seen from the diagram, where some experimental values above 18,000 v. per cm. have been plotted. In weak fields the position is not quite clear, and corresponding measurements will be published later.

Bode's Law and Saturn's Satellites

THOUGH no satisfactory physical explanation has yet been found for Bode's law of the approximately regular progression of the mean distances of the planets from the sun, the law holds good for all the planets except Mercury and Neptune and should not, therefore, be regarded as merely a coincidental truth. If the distance of Mercury itself from the sun is left out of consideration, and Mercury's orbit is taken as the starting-point, then, representing the distance from Mercury's orbit to that of Venus by the number 3, the distance of the other planetary orbits from that of Mercury's are roughly in the geometrical progression 6, 12, 24, etc.

This general relationship seems to apply also to the orbits of satellites if distances are measured from that of the first satellite to those of the others. In the table below, the intervals between the orbits of the satellites of Saturn, as derived from the values given in Prof. R. H Baker's "Astronomy", and as given by a geometric series, are compared; and it will be seen from this that there is good reason for the suggestion of the existence of an undiscovered satellite of the planet between the orbits of Iapetus and Phoebe.

I realize, of course, that the measured distances of Titan and Hyperion from Mimas do not correspond with the distances represented in the geometrical series, but I suggest that this may be due to difficulties in determining the actual distances of these satellites from Saturn on account of the relatively high eccentricity of their orbits. With Titan, the major axis at right angles to a terrestrial observer gives an exaggerated maximum elongation upon which the distance would be based; and with Hyperion, the minor axis at right angles gives a relatively smaller maximum elongation. The result is thus to reduce the difference between the two orbits in both directions.

Mean distances between the orbits of	Observed distances in miles	Distances based on geometrical progression
Mimas and Enceladus	32,700	32,700
,, ,, Tethys	67,700	65,400
,, ,, Dione	118,700	130,800
,, ,, Rhea	211,700	261,600
,, ,, Titan	643,700	523,200
,, ,, Hyperion	804,700	1,046,400
,, ,, Iapetus	2,094,700	2,092,800
,, ,, missing satellite	——	4,185,600
,, ,, Phoebe	7,918,700	8,371,200

However this may be, there is a gap of nearly six million miles between the orbits of Iapetus and Phoebe, and the general order of the progression of the other orbits seems to afford evidence of the existence of a new satellite about two million miles from the orbit of Iapetus and four million miles nearer Saturn than Phoebe. It is just possible that the faint satellite of Saturn, of which Prof. W. H. Pickering reported the discovery in 1905, but which has not since been observed, is the missing body.

Methods of Estimating Mental Factors

MR. M. S. BARTLETT has proposed[1] formulæ for the estimation of mental factors as alternatives to formulæ I have given[2]. My formulæ were arrived at by the ordinary regression method. Bartlett's estimates and the regression estimates attain different ends, and it is agreed that each method is correct in the right place. The regression estimates minimize the squares of the discrepancies between the estimates and the true values, summed over the population of persons. Bartlett's estimates minimize the squares of a man's *specific* factors, summed over the tests. If the scores expressed in matrix notation as linear functions of the true factors are

$$Z = MF = M_0F_0 + M_1F_1$$

the two sets of estimates, for the common factors only, are

$$\hat{F}_0 = M_0'(MM')^{-1}Z = M_0'R^{-1}Z \text{ (regression estimates)}$$
$$\check{F}_0 = (M_0'M_1^{-2}M_0)^{-1}M_0'M_1^{-2}Z \quad \text{(Bartlett's estimates).}$$

The regression method has the quality that if factors estimated by it are inserted in the specification equation which defines a vocation in terms of factors, the result is the same as a direct regression estimate of vocational ability from the tests.

If estimates, by either method, of all the factors including specifics are inserted into the specifications MF of the test scores, they reproduce the latter exactly. If, however, only the common factors are estimated and used, Bartlett's reproduce the scores better than the regression estimates do. In such a situation, however, the regression method would again *estimate* the original scores from the estimated common factors, and it is the object of this note to point out that if this is done, the results are identical with those produced by Bartlett's method.

If we estimate the quantities Z from the $\hat{F}_0$ only, by the ordinary methods of regression, we get, bearing in mind that the $\hat{F}_0$ are neither normalized nor uncorrelated,

$$\hat{\hat{Z}} = M_0(M_0'R^{-1}M_0)^{-1}M_0'R^{-1}Z = SZ \text{ say.}$$

Whether we simply insert Bartlett's estimates in M_0F_0, or make a regression estimate of the scores from the $\check{F}_0$, we reach the result

$$\check{Z} = M_0(M_0'M_1^{-2}M_0)^{-1}M_0'M_1^{-2}Z = EZ \text{ say,}$$

and we see that the matrices S and E are identical if we use the relations

$$R = M_0M_0' + M_1^2$$

and

$$(M_0'R^{-1}M_0)^{-1} = I + (M_0'M_1^{-2}M_0)^{-1}.$$

Blood Group Inheritance

THE unusual blood group proportions among the Soussoux in French Guinea, found by J. S. de Goldfiem[1] and quoted by R. Elson Dew[2], are inexplicable as a stable distribution on the accepted triple allelomorph theory of blood group inheritance. They are, however, quite consistent with the quadruple allelomorph theory proposed by us[3], if it be assumed that the fourth allelomorph, the AB gene, while rare in most human populations, is the predominant one among the Soussoux. The hypothesis could be tested as follows.

Denoting the four allelomorphic genes R, A, B, D (that is, ab, Ab, aB, AB in our previous notation), let their frequencies be γ, α, β, δ; and let the frequencies of the blood groups O, A, B, AB be r, p, q, s. Then for a stable distribution,

$$\gamma^2 = r,\ \alpha^2 + 2\alpha\gamma = p,\ \beta^2 + 2\beta\gamma = q,$$
$$\delta^2 + 2\alpha\delta + 2\beta\delta + 2\gamma\delta + 2\alpha\beta = s.$$

Hence $\alpha = \sqrt{p+r} - \sqrt{r},\ \beta = \sqrt{q+r} - \sqrt{r},$

$$\gamma = \sqrt{r},\ \delta = 1 - \sqrt{p+r} - \sqrt{q+r} + \sqrt{r}.$$

(For the triple allelomorph theory, there is the additional equation $\delta = 0$.) The data in question are

$$r = 0{\cdot}01,\ p = 0{\cdot}01,\ q = 0{\cdot}09,\ s = 0{\cdot}89,$$

whence $\gamma = 0{\cdot}100,\ \alpha = 0{\cdot}041,\ \beta = 0{\cdot}216,\ \delta = 0{\cdot}642.$

The gene distribution would therefore be

10 per cent R + 4 per cent A + 22 per cent B + 64 per cent D.

Calculation on this basis gives the following results for the offspring of two parents, one being of group AB (in other cases the usual theory applies).

$AB \times AB = 0{\cdot}75\ (AB) + 0{\cdot}025\ (A + 3AB) + 0{\cdot}20\ (B + 3AB) + 0{\cdot}02\ (O + 3AB) + 0{\cdot}005\ [\mathrm{A} + B + 2AB]$,

$A \times AB = 0{\cdot}52\ (AB) + 0{\cdot}26\ (B + 3AB) + 0{\cdot}12\ (O + A + 2AB) + 0{\cdot}085\ [A + AB] + 0{\cdot}015\ [2A + B + AB]$,

$B \times AB = 0{\cdot}49\ (AB) + 0{\cdot}03\ (A + 3AB) + 0{\cdot}07\ (O + B + 2AB) + 0{\cdot}40\ [B + AB] + 0{\cdot}01\ [A + 2B + AB]$,

$O \times AB = 0{\cdot}46\ (AB) + 0{\cdot}06\ (A + AB) + 0{\cdot}31\ (B + AB) + 0{\cdot}15\ (O + AB) + 0{\cdot}02\ [A + B]$.

The notation means that in 75 per cent of families with parents $AB \times AB$ the offspring will be all AB, in 2½ per cent they will be A and AB, expected in the ratio 1 : 3, and so on. On the usual theory, only the family types in square brackets should occur.

It will be seen that the majority of offspring of $O \times AB$ will be either O or AB, that is, anomalies on the usual theory; and a few such anomalies appear in the other three cases. The fourth allelomorph was in fact suggested in order to account for just such anomalies in ordinary populations. Other suggestions which have been made to account for them are *mutation* by various investigators, *crossing-over* by Bauer[4], *trisomy* by Haldane[5]. An examination of blood group pedigrees among the Soussoux would perhaps settle the matter.

Cell Size in Millipedes

THE idea of the constancy of cell size for a particular tissue in different individuals of an animal species has long held sway in zoological literature. This concept has frequently been extended to cover nearly related species[1]. I wish to thank Dr. J. R. Baker, of Oxford, for suggesting this investigation into a case which proved to be at variance with the generally accepted view.

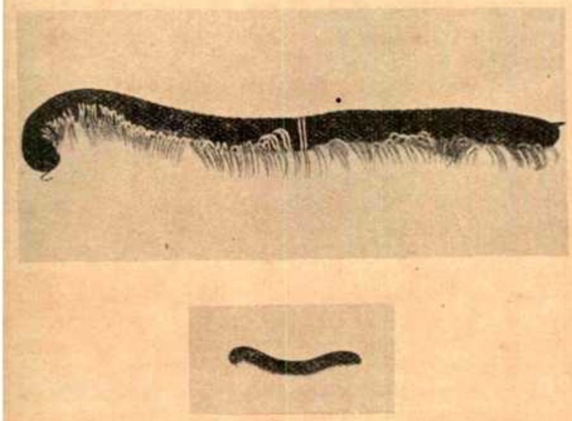

Fig. 1.

ABOVE, *Spirostreptus stenorhynchus*; BELOW, *Cylindroiulus londinensis*. BOTH ABOUT TWO THIRDS NATURAL SIZE.

Spirostreptus stenorhynchus is a very large millipede from Ceylon (Fig. 1). A specimen examined was 13·8 cm. long. The fore-gut (of stomodæal origin) of this animal was fixed in Flemming's fluid with reduced acetic acid content, and transverse sections cut at 5μ. Fat was removed from the sections by immersion in turpentine, and they were afterwards stained in iron hæmatoxylin. These sections were very kindly lent me by Dr. Baker. *Cylindroiulus londinensis*, a British millipede, of average length 2·7 cm., was treated in exactly the same way. It should be noted that these two animals are quite closely related species, both being formerly included in the genus *Iulus*. Flemming's fluid was used since it gives a reasonably good fixation of the nucleus without causing excessive shrinkage in the cytoplasm.

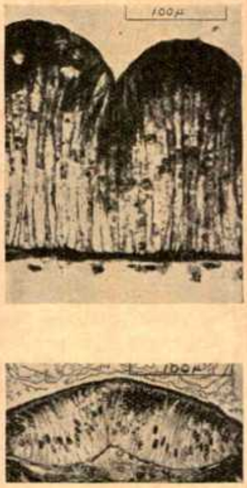

Fig. 2.

FORE-GUT CELLS OF *Spirostreptus* (ABOVE) AND *Cylindroiulus* (BELOW).

In the Ceylon millipede, fifty of the epithelial cells of the fore-gut (see Fig. 2) had an average length of 189 μ, and an average width of 7·8 μ. Corresponding dimensions of the cells of the British millipede were 54 μ and 3·9 μ respectively. It will therefore be seen that the cells of the Ceylon millipede are about fourteen times as large by volume as those of the British millipede. This really enormous difference in cell size (not, however, comparable with the difference in body volume) may perhaps be typical of single-layered epithelia, where symmetry relations according to the size of the lumen would demand larger cells in the larger species.

It may be pointed out, moreover, that W. F. Abercrombie[2] and W. Trager[3], working independently on the larva of the flesh-fly, *Lucilia sericata*, found that the entire growth of the larva from the first instar "is accounted for by increase in size of cells".

The photographs were taken at the John Innes Horticultural Institute by kind permission of Sir Daniel Hall.

Œstrogenic Activity of Certain Synthetic Compounds

IN earlier communications[1,2] two of us have described the œstrogenic activity of certain derivatives of diphenylethane, and in particular it was shown that the introduction of an ethylene linkage between the α and β carbon-atoms of such compounds greatly increased the potency. A number of stilbene derivatives were found to possess a marked activity. Following up this observation, the activity of *p*-hydroxypropylbenzene was next investigated and compared with that of *p*-hydroxypropenylbenzene (anol). The œstrogenic activity of some specimens of anol was found to be of a very high order, but further research indicated that this remarkable potency was probably due to the presence of a more complex substance produced as a by-product during the demethylation of anethole[3]. Recently, the activity of di-anol has been described[4].

In the meantime an investigation had been initiated at Oxford, the object of which was to prepare possible œstrogenic agents bearing a close structural resemblance to œstrone (or œstradiol) but which should be capable of ready synthesis.

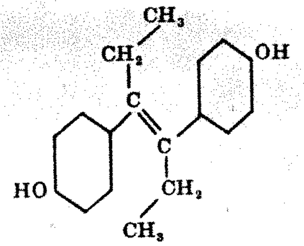
Substance	Dose (mgm.)	Per cent Positive
4-Hydroxy acetophenone	100	Nil
4-Hydroxy propiophenone	10	100
4-Hydroxy butyrophenone	100	100
4 : 4′ : α : β-Tetra hydroxy-α : β-dimethyl-diphenyl ethane	100	100
4 : 4′ : α : β-Tetra hydroxy-α : β-diethyl-diphenyl ethane	0·1	100
	0·01	80
4 : 4′ : α : β-Tetra hydroxy-α : β-di-*n*-propyl diphenyl ethane	10	100
4 : 4′-Dihydroxy-α : β-diethyl diphenyl ethane	10	100
Trans-4 : 10-dihydroxy-1 : 2 : 7 : 8 : 13 : 14 :-hexahydro chrysene..	1	100
4 : 4′ Dihydroxy-α : β-diethyl stilbene in sesame oil	0·0005	100
	0·0004	100
	0·00035	60
,, in water	0·0005	100
	0·0003	80
,, in oil, orally	0·001	80
Diacetate of ,, in oil	0·001	100

In certain directions, especially in the diphenylethane and stilbene groups, we found it convenient to join forces in order to avoid duplication of work.

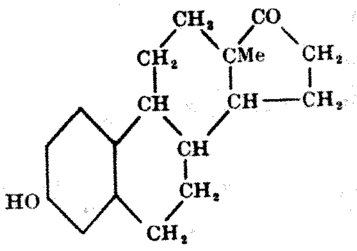
In the preceding table will be found a description of the activity of certain substituted derivatives of 4 : 4′-dihydroxydiphenyl ethane and 4 : 4′-dihydroxystilbene.

It will be noted that by far the most potent substance is 4 : 4′-dihydroxy-αβ-diethylstilbene. This was fully active in ovariectomized rats in a dosage between 0·3 and 0·4 gamma. Comparative tests show it to be between two and three times as potent as œstrone under similar conditions[5]. As can be seen from the table, it is active when dissolved in oil or in aqueous alcohol, or in aqueous solution as the sodium salt. The acetate is also fully active.

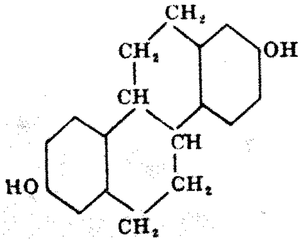
If the formula of this compound, $C_{18}H_{20}O_2$, (I), be written as shown below, the structural resemblance to œstrone, $C_{18}H_{22}O_2$, (II) can be appreciated. It can be seen that it is a possible dimeride of anol.



I



II



III

It is interesting, however, to note that as much as 1 mgm. of dihydroxyhexahydrochrysene (III) is required to produce œstrus in the ovariectomized rat, so that no advantage was gained by the inclusion of the full chrysene structure. The substance had, in fact, an activity of the same order as that of the related 4 : 4′-dihydroxy-αβ-diethyldiphenylethane.

Investigations are in progress upon the pharmacology and biological properties of 4 : 4′-dihydroxy-αβ-diethylstilbene and a series of its acyl derivatives. Other substituents are being introduced at the α and β carbon atoms and the behaviour of the resulting compounds will be reported later.

In view of the fact that 4 : 4′-dihydroxystilbene is the mother substance of a series of œstrogenic agents, we suggest that it may be termed *stilbœstrol*.

The following notes on the preparation of new substances are appended and more detailed publication will follow in another place.

4 : 4′-αβ-*Tetrahydroxy*-αβ-*diethyldiphenylethane* and its *dipropyl analogue* are the pinacols derived from 4-hydroxypropiophenone and 4-hydroxybutyrophenone respectively. The ketones were reduced by means of aluminium amalgam in moist ethereal solution. Crystallized from alcohol, the diethyl compound had m.p. 204–206° ; *diacetate*, m.p. 199–200° ; the dipropyl compound had m.p. 186–187°, *diacetate*, m.p. 199°.

Trans-4 : 10-*dihydroxy*-1 : 2 : 7 : 8 : 13 : 14-*hexahydrochrysene* (III) crystallized from ethyl acetate, m.p. 263–264°, was obtained by the action of a boiling mixture of hydriodic acid (*d* 1·9) and acetic acid on its dimethyl ether[6].

α-*Ethyldeoxyanisoin*, obtained by the action of alcohol sodium ethoxide and ethyl iodide on deoxyanisoin, is a colourless oil, b.p. 192–193° at 0·65 mm. By reaction with ethyl magnesium bromide it affords 3 : 4-*dianisylhexan*-3-*ol*, colourless plates from alcohol, m.p. 115–117°, and this in its turn yields 4 : 4′-*dimethoxy*-αβ-*diethylstilbene* on dehydration in various ways, for example, by the action of acids, acetic anhydride or phosphorus tribromide. The dimethoxydiethylstilbene crystallizes from light petroleum or alcohol, m.p. 123–124°.

The demethylation by many of the usual methods could not be effected. Thus the action of boiling hydriodic acid furnished 4 : 4′-*dihydroxy*-αβ-*diethyldiphenylethane*, a viscous oil, b.p. 189–190° at 0·8 mm. Aluminium chloride reacts with the stilbene so as to form fission products, phenol and a substituted phenol. Demethylation was found to be best effected by the action of alcoholic potassium hydroxide in a sealed tube at 205° and in this way 4 : 4′-*dihydroxy*-αβ-*diethylstilbene* (diethylstilbœstrol) was obtained colourless plates, m.p. 167–168° from aqueous alcohol ; *diacetate*, prisms, m.p. 123–124°. *Dimethylstilbœstrol*, similarly prepared, has m.p. 193–194° after crystallization from ethylene chloride.

The substances, the names of which are italicized above, have all been submitted to elementary analysis and the results are in agreement with theoretica anticipations.

Mechanism of Propagation of Electronic Excitatio Energy, and Photosynthesis in Plants

THE main objection to the concept of a 'photo synthetic unit' in the assimilation process of gree plants has been that the light quanta absorbe primarily would not sustain the numerous transfer from one chlorophyll molecule to another[1]. Recently however, a simple mechanism has been suggested whereby electronic excitation energy could be propagated without loss in a complex of dye molecule

Below, a more complete picture is derived from considerations on the quenching of fluorescence of dyes in solution[3].

In this process an electron of the light absorbing (fluorescent) molecule (D) on being transferred to a higher level (thus constituting the excited form D^*) leaves an empty electronic level behind. If this excited molecule collides with another molecule or ion [acceptor (Acc.)] which possesses an electron, bound with an energy corresponding to this unoccupied level, this electron is transferred to the excited dye, the fluorescence of which is thereby quenched. The molecules in collision constituting a single system, the electron transfer process must be regarded as a quantum mechanical resonance between the states (D^* Acc.) and ($D.^-$ Acc.$^+$) according to the non-adiabatic process[4]

$$D^* + \text{Acc.} \rightleftarrows D^- + \text{Acc.}^+$$

reduced dye (semiquinone).

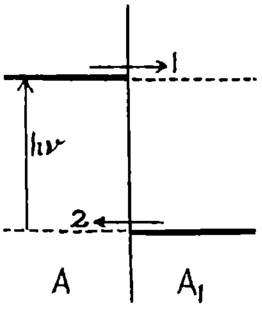
It has been emphasized recently[2] that the double refraction and the probable dichroism of the chloroplasts suggests a regular (crystallic) arrangement of the chlorophyll molecules (Prof. H. Zocher, Prague, has recently been able to prove that the double refraction and dichroism of the chloroplast is partially due to the chlorophyll molecules themselves: private communication) and also strong mutual interaction between the π-electron clouds of the conjugated bond system. A type of such an interaction has been demonstrated in the interesting experiments of Scheibe[5] and Jelley[6] on aggregates of various cyanine dyes. My recent observations that the leucobases of various dyes, for example, methylene blue, Lauth's violet, exert a particularly powerful quenching effect on the fluorescence of the respective dyes show that electronic resonance transfer can easily take place between the excited dye and its leucobase according to

$$D^* + DH^- \rightleftarrows D^- + DH, \ (D^- + H^+ \rightleftarrows DH)$$

(semiquinone)

If a light quantum is absorbed by an electron of one of the dye molecules in the complex, then on account of the strong coupling forces this electron can travel through the lattice. It then represents an excess electron in each molecule through which it passes, thus converting it into a negative ion for a very short time. But at the same time it leaves a positive charge in the originating molecule, and this positive charge can also travel by the transfer of an electron from a neighbouring molecule.

The diagram represents schematically the propagation of electronic excitation energy. Molecule A absorbs the light quantum ($h\nu$). The excited electron is transferred to a neighbouring molecule A_1 ($\rightarrow$1). The electron deficiency in A is made good by another transfer into its lower level (2 $\leftarrow$). As a result the excitation energy is transferred from A to A_1, and the repetition of these processes propagates the energy through the complex.



It is obvious that there exists a close analogy between the above process and the photo-conductivity and related phenomena in halide crystals, which have been extensively studied by R. W. Pohl and his co-workers[7]. It should therefore be possible to apply the experimental methods of Pohl, in a suitably modified form, to the above problem.

Spontaneous Isomerization of Lycopene

DURING some experiments with benzene extracts of various fruits, it was observed that the calcium hydroxide chromatogram frequently, but not in every case, shows a rather brownish orange layer below the lycopene zone. Subsequent experiments have proved that this behaviour of carefully purified lycopene depends on the time which elapses between the dissolution and the adsorption analysis. A fresh solution forms a uniform chromatogram, but if the liquid has been kept at 20° for 1–2 days, the new polyene ("neo-lycopene") is observed; it then forms a very distinctly separated zone in the chromatogram developed with benzene and light petroleum (3 : 1). The pigment content of this layer reached 3 per cent of the total lycopene in experiments of 24 hours duration; the absorption maxima are 511, 479·5, 450 mμ in benzene and 498·5, 468, 440 mμ in petroleum ether. When the benzene solution is kept at room temperature, neo-lycopene is partly transformed into lycopene (or into a very similar dye which cannot be separated from lycopene in the column).

Gillam and his co-workers[1] have published important and highly interesting observations on the isomerization of carotene, which change, according to their data, takes place in the adsorbent itself, during the chromatographic process. In the case of lycopene, we claim that the chromophor spontaneously undergoes a partial rearrangement in certain solvents, where the ordinary lycopene tends to reach an equilibrium with at least one new compound. The progress of this isomerization is a function of the time, and it has nothing to do with a possible subsequent adsorption. The Tswett column only furnishes a suitable method for showing an effect already present in the solution. The isomerization may also be recognized by spectroscopic and colorimetric readings, independently of the chromatographic technique.

As a close study of the change is disturbed by a gradually increasing tendency to autoxidation and bleaching, the observation that the equilibrium between lycopene and neo-lycopene can be reached far more rapidly at an increased temperature was welcome. Examples: (*a*) A solution of 2·6 mgm. of chromatographically homogeneous lycopene in 25 ml. benzene was boiled under reflux for 20 min., during which time the colorimetric value fell to 2·15 mgm. 'lycopene'; the final chromatogram consisted of two main zones, the relative colorimetric strengths of which were 100 lycopene to 62 neo-lycopene. Autoxidation did not occur. (*b*) In a similar experiment performed with a pure solution of neo-lycopene, an increase in the colour value was observed during the heating period from 2 mgm. to 2·35 mgm. 'lycopene', and a chromatogram nearly identical with the foregoing was obtained, namely 100 lycopene to 68·5 neo-lycopene. (The presence of a small quantity of iodine does not alter these proportions considerably.)

At present work is in progress in this laboratory to investigate the stability of other carotenoids under the above conditions, including the isomerization of capsanthine, recently described by Zechmeister and Cholnoky[2]. Further, preliminary experiments show that chromatographically homogeneous β-carotene yields in the calcium hydroxide column a second layer (with α-carotene spectrum), if the freshly prepared solution in light petroleum has been previously kept at 70° for 30 min.; however, the spontaneous change of dissolved lycopene suggests that the stability of the conjugated system of natural carotenoids may be far less than is generally accepted.

Points from Foregoing Letters

Sir C. V. Raman and B. V. Raghavendra Rao submit Fabry-Perot patterns of light scattered by phenol, showing that, with increasing temperature, Doppler-shifted components come increasingly into evidence. In a non-viscous liquid like toluene, both the displaced and undisplaced components are almost completely polarized with the vibrations vertical. In the more viscous phenol the undisplaced vibration is only partially polarized, appearing both in the vertical and horizontal vibrations. The authors consider that the theory which regards the diffusion of light in liquids as due to the reflection of light by regular and infinitely extended trains of sound-waves present in them, must break down in the case of very viscous liquids.

J. F. Allen and H. Jones report experiments which show that associated with a flow of heat in helium II there is a pressure operative in the reverse direction to the heat flow. Under suitable conditions this pressure is great enough to allow the arrangement to be used as a convenient form of helium pump. A possible explanation of the effect, by regarding heat flow as a flow of disorder, is suggested.

By means of a stigmatic spectral apparatus of high resolving power and brilliancy, Dr. B. Kullenberg has determined the relativistic Stark effect, using the line 4686 A. of ionized helium, and submits a diagram showing how the values found experimentally fit the curves theoretically deduced. He finds that if the field is sufficiently strong (above 18,000 volts./cm.) the measurements are in good agreement with the theory.

A table showing the observed mean distances between the orbits of the known satellites of Saturn is given by J. Miller, who points out that they form a rough geometrical progression—a relation which also exists between the relative distances of the planetary orbits (taking the orbit of Mercury as zero line). From his table, Miller infers the existence of a missing satellite of Saturn, between the known satellites Iapetus and Phœbe, at a mean distance of about four million miles from the orbit of the innermost satellite, Mimas.

Prof. G. H. Thomson discusses the sphere of applicability of his 'regression method' of estimating mental factors and of the alternative formulæ proposed by M. S. Bartlett. If only the common factors, excluding specifics, are estimated and used, then Bartlett's formulæ reproduce the scores better than the regression estimates do, but in such a case the regression method would again estimate the original scores from the estimated common factors and would thus give results identical with those obtained by Bartlett's method.

The blood group proportions of the Soussoux of French Guinea appear to be inconsistent with the accepted theory of blood group inheritance. Dr. J. F. Edwards and Dr. I. M. H. Etherington point out that this could be explained if the inheritance depends on four (instead of three) allelomorphic genes. This view of blood group inheritance was previously proposed on other grounds.

H. G. Callan submits photographs showing the relative size of the Ceylon millipede, *Spirostreptus stenorhynchus* and of the English species, *Cylindroiulus londinensis*, and also photomicrographs showing the relative size of the epithelial cells from the fore-gut. The cells of the Ceylon millipede are about fourteen times as large, by volume, as those of the British species.

A table giving the œstrogenic activity of several compounds bearing a close structural resemblance to the sex hormone œstrone, but capable of being readily synthesized, is submitted by Prof. E. C. Dodds, L. Goldberg, W. Lawson and Prof. R. Robinson, together with brief notes indicating the method of preparation of new compounds. The most potent substance is 4 : 4′-dihydroxy-αβ-diethylstilbene, being between two and three times more active than œstrone. The authors propose the name stilbœstrol for the substance 4 : 4′-dihydroxystilbene, which is the mother substance of a series of œstrogenic agents.

From considerations on the quenching of fluorescence of dyes in solution, Dr. J. Weiss suggests a mechanism for the propagation of electronic excitation energy in a complex of molecules. The author considers that the mechanism might be applicable to the process of assimilation by green plants, the energy of the absorbed light quanta passing from one chlorophyll molecule to another, through the transference of an electron which can travel through the lattice.

Lycopene, a natural colouring matter belonging to the carotenoid series, when adsorbed on calcium hydroxide in a Tswett column, shows sometimes an additional brown band. This, L. Zechmeister and P. Tuzson suggest, is due to isomerization taking place when the solution (in benzene or light petroleum) is kept for a few days. Heating renders the isomerization more rapid, an equilibrium being apparently reached.

Research Items

Cave Paintings of Eastern Spain

PROF. H. OBERMAIER, in a review of the palæolithic art of eastern Spain (*L'Anthropologie*, 47, 5–6), reconsiders in the light of recent discovery the evidence bearing on its date, which once generally accepted as Pleistocene and Upper Palæolithic, has recently been assigned by certain archæologists to the Mesolithic period. Prof. Obermaier here argues for the Pleistocene dating. The caves with paintings are found in all the Mediterranean provinces extending southwards from Lerida through Tarragona, Teruel, Castellon, Cuenca, Albaceta, Murcia and Jaen. Though mostly maritime, some caves are situated at some distance from the sea in the mountainous interior. Albarracin (Teruel), for example, is 130 kilometres inland. The resemblance with the Franco-Cantabrian cave art of northern Spain, admittedly Pleistocene, is considerable, the most important difference being the prominence of the human form in eastern Spain, rare or absent in the north, and throwing a remarkable light on costume, weapons, etc., as well as on mode of life, warfare, and even belief. Apart from this resemblance, the argument for the age of the eastern paintings must depend upon the character of the animals which are depicted, The fauna of northern Spain is poorer than that of the cave art of France; reindeer, rhinoceros and mammoth are absent. In central, southern and eastern Spain, northern species do not appear at all, while the southern fauna had already disappeared. What remains are the species of general distribution, ibex, deer, horse, Bovidæ, boar, lynx, rabbit. The animal figures of the east are very much reduced in size, but for the most part are clearly to be distinguished, though some on this account are ambiguous in form. Nor were the painters always meticulously careful in detail; nevertheless it has been possible to identify a number of species with certainty, while other identifications are probable. None is domesticated, and all belong to a palæolithic fauna. Two further arguments are adduced: first the resemblance to the *art mobilier* of the cavern of Parpallo, Valencia, from proto-Solutrean and Solutrean levels, and secondly the relation of its schematic forms to the Azilian art in a line of descent in schematization.

Vitamin B_6 and Flavin Phosphoric Acid

A SHORT article in NATURE on December 18, 1937, p. 1070, summarized the present position with regard to the vitamin B_2 complex. It was there mentioned that 'vitamin B_2' is now regarded as a complex of three distinct factors—namely, (1) the pellagra-preventing (P.P.) factor, which cures pellagra in man, monkeys or pigs, and the so-called black-tongue of dogs; (2) lactoflavin (known as 'riboflavin' in the United States), which is needed for the growth and well-being of rats, and probably of many other species; and (3) vitamin B_6 (the so-called 'rat acrodynia', or 'rat pellagra' factor) which prevents certain characteristic skin lesions in rats. Work on the chemical characterization of these three constituents of the 'B_2 complex' has made rapid progress of late. Lactoflavin was already synthesized in the laboratory a year or more ago. In the issue of NATURE referred to, mention was made of the identification of the pellagra-preventing vitamin (or pro-vitamin) with nicotinic acid. The matter is now taken a step further by the recent announcement in the current issue of *Pflüg. Arch. ges. Physiol.*, by Karrer, Laszt and Verzár that vitamin B_6 deficiency in rats is cured by 'flavin phosphoric acid'. The close chemical relationship thus suggested between two constituents of the vitamin B_2 complex, vitamin B_6 and lactoflavin, raises many interesting points which will no doubt be the object of further study.

Pennatulacea of the John Murray Expedition

IN a recent report, Prof. Hickson describes several interesting forms although none is actually new to science (The John Murray Expedition 1933–34. Scientific Reports, 4, No. 5. The Pennatulacea, by Prof. Sydney J. Hickson, 1937). Numbers of certain species, hitherto only known from a single specimen, are present, providing material for the study of growth and variation, and in one case (*Umbellula huxleyi*) it is possible to prove that several previously described species are only growth stages or varieties of one widely distributed species. *Umbellula huxleyi*, like many others from the deep sea, is now shown to have a very wide geographical distribution, extending perhaps as far east in the Pacific Ocean as Hawaii. The remarkable *Chunella gracillima*, regarded previously as very rare, was found in great numbers in the Pemba Channel, where it was first discovered by the *Valdivia* Expedition. This was associated in both collections with *Funiculina quadrangularis*. The only other locality in which *Chunella gracillima* has been found is in the Bali Sea in the Malay Archipelago, where it is also associated with the only specimen of *Funiculina* obtained during the voyage of the *Siboga*. The sexual condition of all species wherever possible is noted.

Crabs from Singapore

No. 13 of the *Bulletin of the Raffles Museum*, Singapore, Straits Settlements (Aug. 1937), contains many papers of interest, two of which deal with the Brachyura: "Notes on a Collection of Swimming Crabs (Portunidæ) from Singapore" by Chià-Jui Shen, and "On the Crabs of the Family Ocypodidæ in the Collection of the Raffles Museum" by M. W. F. Tweedie, curator of the Museum. There are many swimming crabs in this region, but all belong to the sub-family Lupinæ, the groups Lupocycloida and Podophthalmoida each being represented by one species and the group Lupoida by twenty-six. It is shown that the Portunidæ are more abundantly represented in the warmer regions than in the cooler. This paper is illustrated by excellent figures of many of the species, and two new species of *Neptunus* are described. The material for the second paper was collected for the most part mainly in mangrove swamps around Singapore Island and on the east and west coasts of the Malay Peninsula. A key is given of the species (19 and one sub-species) of *Ilyoplax* and their geographical distribution, and there is one new species described. The new genus, *Pseudogelasimus*, closely related to *Ilyoplax*, is proposed for a single male specimen with peculiarly long eyes and associated broadening of the carapace and very unequal chelæ. A large number of other species belonging to other genera are described.

Genitalia of Orthopteroid Insects

No. 5 of vol. 96 of the Smithsonian Miscellaneous Collections (1937) is devoted to a comprehensive account of the male genitalia of orthopteroid insects, written by Mr. R. E. Snodgrass of the U.S. Bureau of Entomology. The author points out that the external genitalia in these insects are primarily phallic organs. Accessory parts or periphallic (clasping) organs are but little developed and when present they are, for the most part, secondary formations having no apparent relationship in the different groups. The true appendages of the ninth segment are, however, retained in many families as a pair of small styli which are carried on the hind margin of the 9th sternum. It is only in the Grylloblattidæ that these styli retain their bases or coxopodites (coxites): in all other families these basal elements are fused with the sternum. The median penis of Ephemeroptera and some Dermaptera is a different structure from that of the Orthoptera because it is clearly a product of the union of two separate penes, each containing an outlet duct. The median penis of Orthoptera, and probably of most pterygote insects, is not produced by the union of two primary organs, each containing part of a primitive lateral duct. The external and internal genitalia, and their homologies, are discussed in great detail in all the Orthopteroid orders and related groups. Mr. Snodgrass's account is accompanied by numerous original figures notable for their clarity and detail. At the end of the memoir there is a very full bibliography of the literature on the subjects concerned.

Photosynthesis of Coffee Leaves under Natural Conditions

F. J. NUTMAN has recently described a method of studying the carbon dioxide absorption by individual leaves under field conditions (*Ann. Bot.*, N.S., **50**, July 1937), and by the use of this method supplies evidence that these leaves assimilate more vigorously in shade than in full sunlight under tropical conditions in the northern province of Tanganyika Territory. The reasons for this behaviour are discussed; it is concluded that stomatal closure in direct sunlight is the most probable explanation and experimental evidence in support of this conclusion is promised in a subsequent communication. These conclusions have some general importance as Nutman has previously shown that the cause of a serious die-back disease of coffee in East Africa may be found in a shortage of carbohydrates.

'Brown Oak' Disease

MR. K. T. ST. G. CARTWRIGHT has investigated the cause of a brown rot of oak and sweet chestnut (*Trans. Brit. Mycol. Soc.*, **21**, Pts. 1 and 2, 68, Oct. 1937). The common beef-steak fungus, *Fistulina hepatica*, is responsible, and though it may cause little loss of strength in the early stages, a severe attack makes the wood very brittle. The decay does not continue in converted timber, and 'brown oak' is actually easier for the carpenter's work than normal wood. Growth of the fungus is most rapid at 25°–27° C., and the paper suggests that it may obtain its sugar from the breakdown of tannin; the brown material may be a degradation product of lignin and hemicelluloses. Full descriptions of the organism as it appears in wood and upon culture media are given, and two coloured plates aid in realistic portrayal.

Mounds of Arctic America

ALL travellers on the low coastal plain of northern Alaska between Point Barrow and the Mackenzie delta have noted the curious, isolated, more or less conical mounds that diversify the otherwise featureless plain. The Eskimos call such a mound a *pingo*. In a paper in the *Geographical Review* of January 1938, Mr. A. E. Porsild discusses the origin of these and other earth mounds in north-western America and Greenland. He agrees with E. de K. Leffingwell that the Alaskan mounds may be formed by hydraulic pressure. This type is old and shows no sign of recent movement. The freezing of the surface layers over previous unfrozen strata produced conditions favourable to artesian wells. Where downward freezing checked the subterranean seaward flow of water, hydraulic pressure forced upwards the surface layers. A second type of mound, common in the Mackenzie delta, is found in level country or near the border of a lake or former lake basin. This type ranges from a few feet to more than two hundred feet in height and averages 40–75 ft. They often show a median rupture sometimes enlarged to a 'crater' and a well-defined stratification conforming to the slope of the surface. Mr. Porsild suggests that these mounds are formed by local upheaval, due to expansion following downward freezing of a body of water enclosed between bed rock and frozen surface soil. The position of this type of mound supports the theory. When sedimentation fills a lake, freezing of the surface is sure to occur first, thus producing the necessary conditions for the subsequent elevation of the mound. Many of the mounds are in an advanced stage of destruction due to subaerial erosion: some contain small lakes.

Earthquakes of the Channel Islands

SEVEN years ago, Mr. A. E. Mourant issued a valuable catalogue of the earthquakes of the Channel Islands from 842 until 1931 (Société Jessiaise, 50 pp.). To this, he has recently added a supplement (*Trans. Soc. Guern.*, 12, 523–540; 1937) containing accounts of nineteen additional earthquakes from 1640 until 1935, the majority of which originated in centres near the Channel Islands. Of these centres, the one most frequently in action (especially in 1804, 1843 and 1926) is the Jersey focus, situated off the Cotentin coast opposite Jersey. Another important focus, connected with strong earthquakes in 1799 and 1843, lies beneath or near Guernsey. Mr. Mourant notices the interesting point that the occurrence of an earthquake in the Channel Islands tends to be associated with the approach of a depression after an interval of fine weather.

Trade and Counter-trade Winds

MANY interesting facts about the trade and counter-trade winds are revealed in a detailed analysis of eleven years of observations with pilot balloons at Kingston, Jamaica, that is given by S. Proud in Professional Note No. 78 of the Meteorological Office. The natural wind structure above the locally controlled surface wind consists of a layer of trade winds (which blow mainly from east and south-east) several kilometres thick, surmounted by a more shallow transitional layer of veering wind that leads to the counter-trade, which last is an extension southwards and upwards into the tropics of the westerlies of temperate latitudes. The gradient of temperature between the poles and the equator in the stratosphere, which is the reverse of that at the earth's surface, is such as to weaken and ultimately to reverse the westerlies at great heights above the tropopause. Such reversals were found on three occasions, one during the remarkable ascent to 26 km. (87,000 feet) of October 6, 1928, which showed south-easterly winds from 20 to 26 km. Apart from day to day variations in the wind structure, which are considerable, there is the well-marked annual oscillation from south to north and back again of the northern boundary of the trade winds at the surface in accordance with the varying declination of the sun but with a lag of about two months, which tends to cause a similar variation in the height at which the counter-trade is reached, this being much less in and around March than in September. The completeness of the reversal is, however, much greater from November until May than in other months. It is shown that the few occasions when the trade wind was absent at all heights were mostly when the main polar front was in the neighbourhood or when a hurricane was developing, generally to the north of Jamaica.

Photochemical Union of Hydrogen and Chlorine

A. J. Allmand, H. C. Craggs and G. V. V. Squire (*J. Chem. Soc.*, 1869; 1937) have carried out investigations on the above subject. In reactions at low pressures in the absence of oxygen the effect of light intensity (I) on the velocity was found to be proportional to I^n, where n varied over the range $0{\cdot}05 - 1$, the latter figure being found at low chlorine pressures, the values becoming lower as the light intensity and chlorine pressure were increased. At sufficiently high pressures, there was an intensity range in which $n = 0{\cdot}5$. The rate of reaction and quantum yield passed through a maximum as the chlorine pressure was increased. Intensive drying of a low-pressure mixture was not found to inhibit the reaction in light, the addition of small quantities of water vapour to the dried gases actually retarding the reaction somewhat. The results are explained by assuming the existence of the radical Cl_3. Reaction chains are terminated by disappearance of Cl and Cl_3 both on the walls and, without triple collisions, in the gas phase.

Solubilities of Citric and Tartaric Acids

SINCE the information on the solubilities of citric and tartaric acids in water was very incomplete, these properties have been reinvestigated by L. H. Dalman (*J. Amer. Chem. Soc.*, 59, 2547; 1937) who gives values from 0° to 100° for both acids. The solubility curve for tartaric acid is a straight line representing solutions in equilibrium with anhydrous tartaric acid, this line being represented by the equation $s = 51{\cdot}8573 + 0{\cdot}2643\,t$, where s is solubility in per cent by weight and t is temperature. The solubility curve for citric acid consists of two straight lines which intersect at 35·8°; below this temperature, citric acid monohydrate exists, whilst above it, anhydrous citric acid is the stable phase. The solubility curve for the monohydrate is represented by the equation $s = 48{\cdot}9559 + 0{\cdot}5231\,t$, and that for the anhydrous acid by $s = 57{\cdot}8564 + 0{\cdot}2616\,t$.

Improvements in Cinema Sound Reproduction

THE improvements in the quality of the sound reproduction in the cinemas of Great Britain has greatly increased since its inception ten years ago. In the chairman's address to the Radio Section of the Institution of Electrical Engineers given on November 3, these developments are broadly traced out and an indication is given of the trends of further research. The average human ear, it was stated, can appreciate sounds having frequencies lying between 16 and 20,000 cycles per second. The early equipments of 1928–30 had a frequency range lying between 100 to 4,000 C.P.S. and a power range of 30 'decibels'. At 1,000 C.P.S. a power range of 130 decibels can be appreciated lying between the threshold of audibility and maximum audibility. The difficulties of maintaining a recording power range of 30 decibels on the film led to serious alterations in the character of the recorded sound. Distortion was also introduced by the film propelling mechanism, which consisted of a gear-wheel and sprocket-tooth. A harsh and throaty reproduction was thus produced. The volume range of the film is expressed as the ratio of the amplitude of the maximum signal that can be recorded on the track to the amplitude of the background noise from the film itself. If the background level is 30 decibels below the maximum signal it is inaudible. The elimination of ground noise was the aim of the earlier inventors, and this led to considerable improvements. The extension of the frequency range of the amplifiers has been from 100–4,000 to 50–8,000. The loud speaker range has been extended to 30–8,000 and the harmonic distortion has been greatly reduced. The amplifiers and loudspeakers are now in an advanced state of development. Cinema acoustics are becoming better understood, but it is not yet possible to predict with confidence the overall characteristics of a well-tried equipment when installed in a new auditorium.

Comparison of Right Ascensions

W. W. H. GREAVES has recently issued a paper "A Comparison between the Right Ascensions of the Second Greenwich Catalogue of Stars for 1925·0 and of the FK3" (*Mon. Not. Roy. Astro. Soc.*, 98, 1, Nov. 1937). The systematic differences in right ascension between the Second Greenwich Catalogue for 1925·0 and the *Dritter Fundamentalkatalog des Berliner Astronomischen Jahrbuchs* (usually referred to as "FK3"), have been determined, and this complete systematic difference $\Delta\alpha$ is given by $\Delta\alpha = \Delta\alpha_a + \Delta\alpha_\delta$, the terms on the right-hand side being taken from tables. It has been found that the $\Delta\alpha_a$ values include periodic terms which involve the tangent of the declination, and it is suggested that this may be attributed to a periodic error in the determination of the azimuth of the Airy transit circle. In the previous Greenwich Catalogue, a similar effect was noticed, but opposite in phase. This change appears to be associated with a change in the system of determining azimuth. For the first catalogue, the azimuths were based on the observations of nine stars situated within 4° of the north pole, but when the second catalogue was commenced in 1922, the azimuth list was extended down to declination + 45°, and at present comprises 79 stars. This appears to have introduced a noticeable change in the periodic azimuthal term, but it is admitted that the precise instrumental origin of the change is obscure. It is suggested that a diurnal oscillation in azimuth with a seasonal change in its amplitude might be a possible contributory cause.

A Simplification of Maxwell's Equations in Conformity with the Flux-cutting Principle

By Dr. C. V. Drysdale, C.B., O.B.E.

DURING the last thirty years, the question as to whether electromagnetic induction is caused by the change or by the cutting of magnetic flux has been debated at intervals. Faraday's rotating disk experiment and the later experiments of Blondel[1] and of Messrs. Cramp and Norgrove[2], as well as Prof. H. A. Wilson's experiments with moving dielectrics[3], all appear definitely to favour the flux-cutting hypothesis; and Rowland's experiments with revolving electrostatically charged disks[4] indicated that a magnetic force is similarly induced by the cutting of an electric field. There seems little doubt that Faraday himself believed that electromagnetic induction was produced by the cutting of his magnetic "lines".

The four fundamental equations of Maxwell for a non-conducting dielectric medium:

$$\text{(i) } 4\pi D = \varepsilon E, \qquad \text{(iii) } -\operatorname{curl} E = \dot{B},$$
$$\text{(ii) } B = \mu H, \qquad \text{(iv) } \operatorname{curl} H = 4\pi\dot{D},$$

(where E and H are the electric and magnetic forces, D and B the corresponding displacement and induction; and ε and μ the dielectric constant and permeability of the medium, respectively) were avowedly intended to put Faraday's concepts into mathematical form; but the two latter equations are obviously based on the change of flux principle, as they give the line integrals of the electric or magnetic forces around unit area due to the rate of change of magnetic or electric flux through that area, and not the actual forces themselves. These two equations are not only difficult to comprehend and to visualize physically, but also they are difficult of application owing to the complex differential equations to which they give rise; and, if the flux-cutting principle is the true one, they are not completely fundamental.

It is easy to show that a simple transformation of the Maxwellian equations divests them of all complexity and harmonizes them with the flux-cutting principle. For if we write $j\frac{\partial}{\partial x}$ for curl, equation (iii) becomes

$$-j\frac{\partial E}{\partial x} = \frac{\partial B}{\partial t} = \frac{\partial B}{\partial x}\frac{dx}{dt} = V\frac{\partial B}{\partial x},$$

from which $E = jVB$, if $E = 0$ when $V = 0$. This is equivalent to the dynamo designer's formula E.M.F. = lVB for the electromotive force in a conductor of length l moving transversely with velocity V across a magnetic field B, since the electric force E is the electromotive force per unit length. The quadrantal versor $j = \sqrt{-1}$ simply implies that the electric force is perpendicular to the plane containing the motion and magnetic flux, and does not affect its magnitude.

Similar treatment of equation (iv) gives us $H = -j4\pi VD$, which is obviously proportional to the rate of cutting the electrostatic flux and is in accordance with the results of Rowland's experiments; and if we harmonize the electrostatic and magnetic units by writing J for $4\pi D$, which implies 4π electrostatic "lines" of induction per unit charge, in conformity with 4π magnetic lines per unit pole, Maxwell's equations become:

$$\text{(i) } J = \varepsilon E, \qquad \text{(iii) } E = jVB,$$
$$\text{(ii) } B = \mu H, \qquad \text{(iv) } H = -jVJ,$$

for an isotropic dielectric medium moving with velocity V, or:

$$\text{(ia) } J = \varepsilon E, \qquad \text{(iiia) } E = -jVB,$$
$$\text{(iia) } B = \mu H, \qquad \text{(iva) } H = jVJ,$$

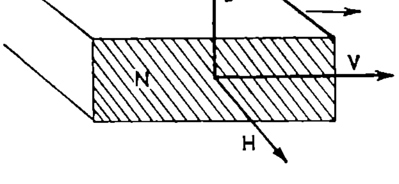
for a stationary isotropic dielectric and moving fields. The change of sign in the last two equations is equivalent to the change from the 'right hand' to the 'left hand' rule in changing from moving armature to moving field machines.

These equations are all of the same simple linear form, and are easily grasped, memorized and handled, since the last two may be summed up as:

Induced $\left\{\begin{matrix}\text{electric}\\ \text{magnetic}\end{matrix}\right\}$ force is equal to the rate of cutting $\left\{\begin{matrix}\text{magnetic}\\ \text{electric}\end{matrix}\right\}$ lines.

APPLICATIONS TO ELECTROMAGNETIC WAVE PROPAGATION

A few applications to the theory of electromagnetic wave propagation will serve to show their convenience. Combining (iia) and (iiia), we have $E = -j\mu VH$: and combining (ia) and (iva), $H = j\varepsilon VE$. If we suppose the north pole of a magnet moving transversely through an isotropic non-conducting medium with velocity V, as shown in the accompanying diagram, its magnetic force H will be directed horizontally forward, and according to the first of these combined equations, it will induce an electric force in the medium, $E = -j\mu VH$, directed vertically upwards. By the second combined equation, this electric force will in turn induce a magnetic force $H^1 = j\varepsilon VE = \varepsilon\mu V^2H$, since $j^2 = -1$, so that H^1 will be in the same direction as H, and will therefore tend to strengthen the magnet, just as a capacitance load on an alternator causes a rise of E.M.F. by strengthening its magnetic field. The transverse motion of the magnet therefore produces a forced electromagnetic disturbance or wave in the medium, and as the velocity of the magnet is increased the



magnetic and electric fields will increase, unless H is diminished to $H - H^1 = (1 - \varepsilon\mu V^2)H$, as an engineer reduces the excitation of an alternator to prevent the rise of voltage with a leading current. When $\varepsilon\mu V^2 = 1$, or $V = 1/\sqrt{\varepsilon\mu}$, therefore, H should be reduced to zero, or the magnet may be withdrawn, and the forced electromagnetic wave will persist as a free one in which E and H are maintained by their reciprocal inductive interactions, and it will travel forward unchanged with the velocity $V = 1/\sqrt{\varepsilon\mu}$, which is Maxwell's expression for the velocity of propagation of electromagnetic waves, including light. Since $E = -j\mu VH$, and $V = 1/\sqrt{\varepsilon\mu}$, $E = -j\sqrt{\mu/\varepsilon}\,.\,H$: so that as ε and μ are constants for all dielectric media, E and H must have a constant ratio and hence have the same wave-form and phase.

The formula $E = -jVB = -j\mu VH$, which represents the rate of cutting magnetic lines, is already familiar to scientific and technical students, but the corresponding formula $H = jVJ = j\varepsilon VE$, which represents the rate of cutting electric lines, is not; so that it may be well to show that it is in conformity with known elementary principles. A vertical electric force E in a dielectric medium produces an upward electrical displacement D such that $4\pi D = \varepsilon E$, so that if we consider the magnetic field H as stationary while the medium is flowing past it with velocity V in the opposite sense, the effect of this displacement will be that of two horizontal surfaces, an upper one charged with surface density $+D$, and a lower one charged with density $-D$, both moving with the medium from right to left. The upper surface will be equivalent to a current sheet of intensity VD per unit breadth flowing from right to left, and the lower to a similar current sheet flowing in the opposite sense since it is negatively charged; so that the total effect will be that of a current sheet or solenoid of intensity VD per unit length circulating round the region of electric displacement in a counter-clockwise direction, which must produce a magnetic force H in that region equal to $4\pi VD = \varepsilon VE$ and directed horizontally forward, and hence $H = -j\varepsilon VE = -jVJ$, the negative sign being due to our dealing in this case with a moving medium instead of moving fields. Since for a moving medium $E = jVB = j\mu VH = \varepsilon\mu V^2E$, E and H will be mutually maintained when the velocity of the medium $V = 1/\sqrt{\varepsilon\mu}$, so that if an electromagnetic disturbance is once started, it will persist unchanged in magnitude and position and will therefore be travelling with the velocity $1/\sqrt{\varepsilon\mu}$ relatively to the moving medium. This is analogous to Prof. P. G. Tait's well-known simple demonstration of the propagation of transverse waves along stretched cords or belts.

Crystalline Media. The above equations apply for all isotropic non-conducting dielectrics, but in crystalline media ε varies with the orientation of E, so that the direction of D or J is not in general identical with that of E or perpendicular to the plane of B and V; and as it is only the component of J perpendicular to V which is concerned in the cutting and the induction of H, we must write $H = jVJ \sin\theta$, or $[VJ]$, where θ is the angle between J and V, and the square brackets imply the vector product of V and J. Similarly we may write $E = -[VB]$, but since the permeability of dielectric media does not differ materially in any direction from that of space, B is simply μH and is always in the direction of H and perpendicular to V, so that we may write $E = -jVB$ or $-[VB]$ as we prefer. Hence the fundamental equations for all dielectric media are:

$J_1 = \varepsilon_1 E_1$ etc., $B = \mu H$, $E = -[VB]$, and $H = [VJ]$, which lead to the following six simple algebraical equations:

$$\begin{aligned}
E_1 &= V_3B_2 - V_2B_3 = \mu(V_3H_2 - V_2H_3)\\
E_2 &= V_1B_3 - V_3B_1 = \mu(V_1H_3 - V_3H_1)\\
E_3 &= V_2B_1 - V_1B_2 = \mu(V_2H_1 - V_1H_2)\\
H_1 &= V_2J_3 - V_3J_2 = \varepsilon_3V_2E_3 - \varepsilon_2V_3E_2\\
H_2 &= V_3J_1 - V_1J_3 = \varepsilon_1V_3E_1 - \varepsilon_3V_1E_3\\
H_3 &= V_1J_2 - V_2J_1 = \varepsilon_2V_1E_2 - \varepsilon_1V_2E_1
\end{aligned}$$

where the suffixes imply the components in the three axes of the crystal.

Combining these we have:

$$\begin{aligned}
\{1-\varepsilon_1\mu(V_2^2+V_3^2)\}\,E_1+\varepsilon_2\mu V_1V_2E_2+\varepsilon_3\mu V_1V_3E_3 &= 0\\
\{1-\varepsilon_2\mu(V_1^2+V_3^2)\}\,E_2+\varepsilon_3\mu V_2V_3E_3+\varepsilon_1\mu V_1V_2E_1 &= 0\\
\{1-\varepsilon_3\mu(V_1^2+V_2^2)\}\,E_3+\varepsilon_1\mu V_1V_3E_1+\varepsilon_2\mu V_2V_3E_2 &= 0
\end{aligned}$$

Hence if the propagation is along axis 1, $E = 0$, $(1 - \varepsilon_2\mu V_1^2)E_2 = 0$, and $(1 - \varepsilon_3\mu V_1^2)E_3 = 0$, which show that the components E_2 and E_3 travel with the velocities $1/\sqrt{\varepsilon_2\mu}$ and $1/\sqrt{\varepsilon_3\mu}$ respectively, so that they must be regarded as separate waves polarized in perpendicular planes. Similarly for propagation along axes 2 and 3, and hence the wave surface must have two sheets intersecting the three axes at radii a and b, a and c, and b and c respectively, where $a = 1/\sqrt{\varepsilon_1\mu}$, $b = 1/\sqrt{\varepsilon_2\mu}$, and $c = 1/\sqrt{\varepsilon_3\mu}$.

It should be noted that since the directions of J and E are not in general the same, the wave cannot be self-maintained unless E, J and V are coplanar, as if J is deviated out of the plane EV, $H = [VJ]$ must be perpendicular to the plane JV and the induced electric force $E_1 = -\mu[VH]$ will be in the plane JV instead of the plane EV and cannot be coincident with E for any value of V. But for any direction of E there will be a plane containing E and J, so that if V is in this plane and perpendicular to E, the induced electric force will be identical with E for a certain value of V, and hence a plane polarized beam can be transmitted in that plane. For E, J and V to be coplanar the scalar product $(EJV) = (\varepsilon_3 - \varepsilon_2)E_2E_3V_1 + (\varepsilon_1 - \varepsilon_3)E_1E_3V_2 + (\varepsilon_2 - \varepsilon_1)E_1E_2V_3$ must be zero, and it is easy to show that this condition can always be satisfied for two perpendicular planes. Hence for any direction of propagation the electric force will be resolved into two perpendicular components both of which will be self-maintaining or transmitted, but in general with different velocities, so that the medium will be doubly refracting and the two components will be plane polarized in perpendicular planes.

Semi-Conducting Dielectrics. In such media an electric force E produces a steady current of density $\dot{D} = \dot{J}/4\pi = gE$, where g is the conductivity, in addition to $J = \varepsilon E$, and hence $J = \varepsilon E + 4\pi g\underset{\cdot}{E}$, where $\underset{\cdot}{E} = \int E dt$. Hence for all isopic semi-conducting media:

$$J = \varepsilon E + 4\pi g\underset{\cdot}{E},\ B = \mu H,\ E = -jVB, \text{ and } H = jVJ,$$

and the induced electric force $E^1 = \mu V^2(\varepsilon E + 4\pi g\underset{\cdot}{E})$, which must balance the impressed electric force E for a self-maintained wave. But the power dissipated in the conductance causes an attenuation or reduction of E as the wave travels forward, and since the displacement of the dissociated ions depends on the previous variations of the electric force, we shall only obtain the steady periodic condition by differentiating twice with respect to time, and writing $\frac{d^2E^1}{dt^2} = \mu V^2(\varepsilon E + 4\pi gE)$. The variations on the right-hand side depend simply upon the changes of E with time, irrespective of the motion of the wave in space, but the induced electric force E^1 is caused by the cutting due to the motion and we must therefore write

$$\frac{dE^1}{dt} = \frac{\partial E^1}{\partial x}\frac{dx}{dt} = V\frac{\partial E^1}{\partial x}, \text{ and } \frac{d^2E^1}{dt^2} = V^2\frac{\partial^2E^1}{\partial t^2},$$

which gives us $\frac{\partial^2E}{\partial x^2} = \varepsilon\mu\frac{\partial^2E}{\partial t^2} + 4\pi g\mu\frac{\partial E}{\partial t}$ for a self-maintained wave.

This relation arises directly from the Maxwellian equations, but the above treatment is not only more simple but also gives a clear idea of the physical processes involved, and it directs attention to the question of the actual displacement of the dissociated ions which may give rise to transients.

Lorentz Theory of Moving Media. According to the ionic constitution of matter, the absolute dielectric constant of a medium is $\varepsilon_0 + \varepsilon_i$, where ε_0 is the absolute dielectric constant of space, and ε_i that due to the displacement of the ions, which is equal to $4\pi\Sigma\frac{Ne^2}{K-m\omega^2+jb\omega}$, where N is the number of ions of charge e, mass m, coupling constant k, and damping coefficient b per unit volume, for a sinusoidal disturbance for which ω is 2π times the frequency; and this in conjunction with the above equations leads to Drude's theory of dispersion. But if the medium is moving and carrying the ions along with it with a velocity v in the direction of propagation, an electromagnetic disturbance travelling with velocity V only travels with velocity $V - v$ relatively to the ions. The conditions are therefore similar to those in an induction motor in which the revolving field cuts the stationary stator bars with a velocity V and the revolving rotor bars with velocity $V - v$, the former being represented by the stationary ether between the ions, and the latter by the moving ions. If a magnetic field H is moving with velocity V through the medium, it will induce an electric force $E_0 = -j\mu VH$ acting on the stationary ether, and $E_i = -j\mu(V - v)H$ acting on the ions; and hence $J_0 = -j\varepsilon_0\mu VH$, and $J_i = -j\varepsilon_i\mu(V - v)H$. These electric inductions will in turn induce magnetic forces $H_0 = jVJ_0 = \varepsilon_0\mu V^2H$ in the ether and $H_i = \varepsilon_i\mu(V - v)^2H$ due to the ions, so that the total induced magnetic force will be $H^1 = H_0 + H_i = \mu\{\varepsilon_0V^2 + \varepsilon_i(V - v)^2\}H$, and the wave will be self-maintaining if $H^1 = H$, or $\varepsilon_0\mu\{V^2 + \frac{\varepsilon_i}{\varepsilon_0}(V - v)^2\} = 1$.

But $\frac{\varepsilon_0 + \varepsilon_i}{\varepsilon_0} = 1 + \frac{\varepsilon_i}{\varepsilon_0}$ is the ordinary relative or measured dielectric constant of the medium $\varepsilon = n^2$, where n is the refractive index of the medium for the frequency of the disturbance, and hence $\varepsilon_i/\varepsilon_0 = n^2 - 1$ and $V^2 + (n^2 - 1)(V - v)^2 = 1/(\varepsilon_0\mu) = c^2$, where c is the velocity of propagation in space.

To the first order of $v/V = nv/c$, this gives us:

$$V = \frac{c}{n} + \frac{n^2 - 1}{n^2}v,$$

if the source is moving with the medium, or

$$V = \frac{c}{n} + \left(\frac{n^2 - 1}{n^2} - \frac{\lambda}{n}\frac{\partial n}{\partial\lambda}\right)v$$

for a stationary source and moving medium.

These are Lorentz's relations for the propagation of electromagnetic waves through moving dispersive media, which have been confirmed by the moving-water experiments of Zeeman and give a theoretical basis for the Fresnel drag coefficient $(n^2 - 1)/n^2$.

The above applications will suffice to show that these simple equations lead to results which are in agreement with those derived from the Maxwellian equations, and their simplicity and fundamental correctness of principle may lead to useful extensions, especially as they focus attention on the physical interactions involved. For closed circuits of rigid conformation where we are concerned only with the total induced electromotive force, the ordinary rate-of-change or 'transformer' formula $E = -\partial N/\partial t$ is correct and more convenient, and even for deformable circuits I have shown[5] from energy considerations that the most convenient general formulæ for calculating the force or torque in such systems are $f = \frac{1}{2}i^2\frac{\partial L}{\partial x}$ or $T = \frac{1}{2}i^2\frac{\partial L}{\partial\theta}$, where f is the force, T the torque, and L the inductance of the circuit; but it seems to be proved beyond doubt that electric and magnetic forces can only be induced by the cutting of magnetic or electrostatic fields, so that even in closed circuits it appears that any change of flux must involve the actual cutting of magnetic or electrostatic "lines", although it may be difficult to visualize the process in many cases. The simplified Maxwellian equations, based on the flux-cutting or 'dynamo' principle, appear to be the fundamentally correct ones; and, as they are much more simple to handle and comprehend in dealing with radiation problems, it would seem that they should be adopted.

SUMMARY

Faraday's rotating disk experiment and the later experiments of Blondel, Cramp and Norgrove, and H. A. Wilson all indicate that magneto-electric induction is caused by the cutting of a magnetic field rather than by its rate of change; and Rowland's experiments with rotating electrostatically charged disks similarly indicate that a magnetic force is induced by the cutting of an electrostatic field. The fundamental Maxwellian equations are based on the change of flux principle, but it is here shown that a simple transformation of these equations brings them into harmony with the flux-cutting principle and reduces them to four simple algebraic or vector equations which enable radiation problems to be treated with great simplicity and easy grasp of the physical processes involved. Application of these equations to the propagation of electromagnetic waves in isotropic and crystalline dielectrics and in semi-conducting and moving media show that they lead to the same results as the Maxwellian equations.

Food of the Herring*

TWO researches on food of adult herring have recently been published. It is interesting to compare the results, although Savage's work covers March–October only, chiefly May–August, and Jespersen's was continued throughout the year. The period covered is the same, from 1931 until 1934 and 1935. In 1931 the herring fishery at Bornholm was very poor in both number and size of fish and it was found that those feeding were remarkably few in number, a fact probably correlated with the scarcity of food, especially copepods. Off Shields and in the northern North Sea, however, the year 1931 was a rich feeding year, due almost entirely to the abundance of *Calanus*. Although *Calanus* is such an important herring food in many regions it is not present at Bornholm (the low salinity accounting for its absence), the chief copepods being *Pseudocalanus elongatus*, eaten during the first half of the year, and *Temora longicornis* and *Eurytemora hirundoides* (taken together), on the whole even more important, eaten throughout the year, but especially in the winter half.

Copepods form the main food of the herring in both districts. There is little feeding during the great East Anglian autumn fishery and in the Bornholm herrings it is lowest in August-October, in and just after the spawning season. In both districts it is highest in spring and early summer and the main food consists of copepods, but *Oikopleura* occupies an important position in some years as food in the North Sea and is not present at all in Bornholm. *Ammodytes*, however, was frequently eaten both at Bornholm and off Shields although absent from farther north. Whereas, however, it is eaten chiefly in winter and early spring at Bornholm it seems to be eaten indiscriminately at other times of year at Shields. In fact, there is a more marked difference in the seasonal food at Bornholm than in the North Sea with the exception of the all-important *Calanus*, the maximum of which is in all years in May.

In the Bornholm herring in spring the food is principally copepods and young fish, in summer principally copepods and cladocerans, in autumn copepods and in some degree cladocerans, in winter, besides copepods, chiefly larger crustaceans. In the North Sea the principal food, varying in different years, is *Calanus* in spring and summer, *Temora longicornis* in late summer, *Oikopleura* usually in spring and early summer, whilst other copepods, cladocerans and larger organisms, such as *Sagitta*, Crustacea and *Ammodytes* occur at different times, varying in different years. The curve shows a maximum of food, due to *Calanus*, in May, and a characteristic smaller secondary peak at the end of August and beginning of September due to decapod larvæ, *Oikopleura*, *Sagitta*, Schizopods, *Limacina* or Amphipods, *Temora* and, occasionally, *Calanus*.

Calanus was the principal item in the food of the Shields herring and the date and size of its maximum in the plankton appeared to have a close relation with the appearance and size of the shoals, an early maximum being associated with abundant herring and a late maximum with poor catches.

It is an interesting fact that the 1931 year-class of herring, that is to say those fish spawned after the rich feeding of that year, has been a very poor one since it entered the shoals as three-year-old fish in 1934; on the other hand, the fish spawned after the poor feeding of 1932 have proved to be a very rich year class.

Malnutrition and Maternal Mortality

SINCE 1934, the National Birthday Trust Fund has been engaged in an attempt to reduce the high maternal mortality rates which prevail in most of the 'special areas', and some interesting results have been obtained in the last two years. A general outline of the schemes which have been applied in Glamorgan, Monmouth and Durham and the results obtained are described by Lady Williams in *Public Health* (50, 231, and 51, 59; 1937).

The schemes involved additional medical facilities with or without a distribution of free foodstuffs to necessitous mothers. The additional food comprised one pint of milk daily (from the local authority) with Ovaltine and Marmite from the National Birthday Trust Fund, and either Brandox Essence of Beef or Dorsella dried milk. Analysis of the results shows that whereas increased medical facilities alone produced a definite reduction in the puerperal death-rate—to about one third– from 'other causes', the death-rate from 'sepsis' was less affected. On the other hand, in the groups receiving the extra food a remarkable reduction in the puerperal death-rate from 'sepsis' was observed.

In two and a half years, extra food was supplied to 10,384 expectant mothers: the puerperal death-rate per 1,000 total births was 1·63, being 0·09 from sepsis and 1·54 from other causes. Among 18,854 other cases in the same areas during this period, the puerperal death-rate has been 6·15, being 2·91 from sepsis and 3·24 from other causes. In the preceding seven years, the rate in these districts was 5·63. In the first six months of this year the stillbirth and neo-natal death-rate among the assisted mothers has been approximately half that among cases in the same areas that were not assisted with extra food.

The evidence adduced by Lady Williams suggests strongly that it is the extra food which is responsible for the reduction in the mortality rates: the constituent or constituents have yet to be determined. Since the beef essence and dried milk were not given in all areas, and yet in all areas, among mothers assisted with extra food, the reduction in the mortality rates was observed it appears that the good results must be attributed to the milk, Ovaltine or Marmite.

It is considered that the amount of extra food given was not sufficient, in all probability, to make the diet of the poorest group of mothers who were assisted, more than equal in *quantity* to that of the better-off groups, which did not receive the extra food and acted as controls to the first group. The additional medical facilities, where provided, were available to all groups without regard to income.

It appears, therefore, that the reduction in the maternal mortality rates must probably be due to the *quality* of the extra foods supplied, rather than their *quantity*. The administration of the schemes has now been handed over by the National Birthday Trust Fund to the Research Committee of the Joint Council of Midwifery, by whom further reports will be issued when the results are available.

University Events

CAMBRIDGE.—The Rockefeller Foundation is providing the University with up to £8,000 towards the support of research in the Department of Experimental Medicine over the five-year period, January 1, 1938–December 31, 1942. The funds will be used for the salaries of a pathologist and a psychiatrist, and for supplementing the amount which the radiologist receives from Addenbrooke's Hospital.

N. F. M. Henny, of St. John's College, has been appointed University demonstrator in mineralogy and petrology.

Dr. A. H. Evans has offered to the University his collection of birds' eggs, of which the Director of the Museum writes: "This collection is practically a complete series of the eggs of British birds, and Dr. Evans has spent much time over many years in perfecting it."

The Michael Perkins Prize is awarded to I. L. Mason, of Pembroke College, for his essay entitled "Hot-spring Animals and their Adaptation to Supernormal Temperatures".

M. C. Burkitt, of Trinity College, T. T. Paterson, of Trinity College, and Dr. E. J. Lindgren, of Newnham College, have been appointed delegates to the Second International Congress of Anthropological and Ethnological Sciences, to be held in Copenhagen on August 1–6.

The Board of Management of the Frank Edward Elmore Fund will shortly proceed to the award of a studentship for research in medicine. The studentships are open to male graduates of any university who were born in any country within the British Empire other than Scotland. The student appointed will work in the Department of Medicine in the University, under the direction of the regius professor of physic. The commencing salary will be £300 a year, and the appointment will be for two years in the first instance. Further information may be obtained from the Regius Professor of Physic, Department of Medicine, University of Cambridge, to whom applications should be sent not later than February 28, 1938.

LONDON.—The title of reader in entomology in the University has been conferred on Dr. O. W. Richards, in respect of his post held at the Imperial College—Royal College of Science.

The following doctorates have been conferred: D.Sc. (Economics) on S. J. Madge, an internal student, of the London School of Economics; D.Sc. in botany on F. T. Bennett, an external student; D.Sc. in physics on C. E. Wynn-Williams, an external student.

Science News a Century Ago

The Royal Astronomical Society

IN the report of the Council read at the anniversary meeting of the Royal Astronomical Society on February 9, 1838, it was stated that the printing of the observations made at the Cape of Good Hope by Henderson on the declination of the principal stars and those made by Maclear relative to the reappearance of Halley's comet after its perihelion passage, had been done at the expense of the Government, "an evidence of the encouragement which the Government was disposed to give to science when favourable opportunities presented themselves". The Government had also granted £500 towards the repetition of the Cavendish experiment for determining the density of the earth. A eulogium was passed on the conduct of the British Association for the appropriation of £1,000 towards the improvement and reduction of astronomical catalogues. The report also referred to the arrival of the astronomical and pendulum observations made by the late Lieut. Murphy, during the voyage under Colonel Chesney down the Euphrates, the reduction of which had been undertaken by Sheepshanks and Baily. In conclusion, the Council congratulated the meeting on the flourishing state of the Society and expressed a hope that the same activity and unity of action would continue to influence and pervade their future proceedings. The president at this time was Francis Baily.

Structure of Shells

ON February 9, 1838, John Edward Gray (1800–75) assistant zoological keeper at the British Museum, lectured at the Royal Institution on "The Development, Growth and Structure of Shells". In the course of his lecture he said that the most simple form of crystalline structure is shown in the *Pinnæ* and a few other shells, where the calcareous particles, as they are deposited on the inner surface of the shell, assume a prismatic crystalline form, the crystals being perpendicular to the surface of the shell and extending from surface to surface, except where they are interrupted by any temporary suspensions of the growth of the animal. The most common form of crystalline structure which is found in most univalve shells is far more complicated, and exhibits one of the most beautiful examples of the extremely simple means by which Nature provides for the protection of her creatures. If man, he said, had but observed the process pursued by Nature in the formation of these shells, she would have taught him hundreds of years ago to combine strength with buoyancy in the perfection of naval architecture, instead of leaving it to be a modern discovery. Shells of this structure are formed of three concentric coats closely adhering together.

Biot's Experiments on Tartaric Acid

"M. BIOT has been making some important experiments and observations concerning the effect produced in rays of polarized light by different solutions of tartaric acid, either purely aqueous or combined with other bodies, which combinations alter the rays. The object of these experiments is to establish the laws of each combination, and the learned professor is still devoting his attention to the subject, in the hope of completing the system." (*Athenæum*, Feb. 10, 1838.)

E. Glückauf and F. A. Paneth: Identification and measurement of helium formed in beryllium by gamma rays. While it has been known for some time that the beryllium nucleus, irradiated by γ-rays, emits neutrons, it could not be decided whether the nucleus is thereby transformed into a stable isotope of beryllium of mass eight, or into two helium atoms. By a micro-chemical method, helium was detected in beryllium after irradiation by the γ-rays of radon. In one of the experiments, the number of neutrons simultaneously emitted during the irradiation was determined by measuring the helium produced by these neutrons in methyl borate; a comparison of the two helium quantities showed that the main final product of the γ-irradiation of beryllium is helium and not the beryllium isotope.

J. W. J. Fay, E. Glückauf and F. A. Paneth: Occurrence of helium in beryls. Various specimens of old beryllium metal have been analysed for helium. As the method employed, in spite of its sensitivity, failed to detect any traces of helium, it must be concluded that the spontaneous production of helium in beryllium is less than $1 \cdot 3 \times 10^{-11}$ c.c. of helium per gram beryllium per year. From this figure it follows that the helium content of beryls cannot be explained as a consequence of the spontaneous disintegration of a beryllium isotope of mass eight. In recent years, the helium content of beryls has been attributed to the influence of γ-rays from radioactive minerals in the neighbourhood of the beryls, and to cosmic radiation. From the figures, however, of the preceding paper about the amount of helium produced in beryllium by γ-rays, it follows that the influence of the natural sources of γ-radiation is not nearly sufficient to explain the helium content of beryls. Since, therefore, beryllium does not produce adequate amounts of helium, either under the influence of external radiation or as a consequence of spontaneous disintegration, it seems that the helium content of beryl is not connected with its beryllium content but is due to some other chemical element.

Social Imports of Invention

IN his presidential address to the British Association at Blackpool in 1936, Sir Josiah Stamp, discussing the impact of science upon society, stressed the need for a technique of social adjustment. The soundness of this plea has been emphasized in many subsequent discussions on the relations between science and society and has been confirmed by evidence afforded in such reports as those of the Commissioners for the Special Areas or the surveys of such areas; for example, that of South Wales conducted by the University College, Cardiff.

Despite growing recognition of the importance of some attempt to devise more systematic means of using technical discoveries and improvements and to foresee their direct and indirect effects, there has as yet appeared in Great Britain, however, no systematic study of the direct or indirect repercussions of the impact of invention upon society. The report on "Technological Trends and their Social Implications" (Washington: U.S. Government Printing Office. 1 dollar) which the United States National Resources Committee published in June of last year is accordingly the more welcome, and in issuing an admirable summary of this six hundred page report, Political and Economic Planning (Broadsheet No. 111) has again earned the thanks of all who are considering the problems which arise from the impact of science upon society.

The report in question was prepared by a special scientific sub-committee and represents a major attempt to forecast the limits of new inventions which may affect living and working conditions in the United States in the next ten to twenty-five years. It indicates some of the problems inevitably involved in the adoption and use of these inventions and emphasizes the importance of national efforts to bring about prompt adjustment to those changing situations with the least possible social suffering and loss, and sketches some of the lines of national policy required.

Much of the matter contained in the report is relevant to European as well as to American conditions, and the lack of attention which the report has received is a further indication of the absence of effective means for the exchange of information and the interpenetration of thought on problems of common concern to the two chief English-speaking democracies. PEP itself is indeed now attempting to improve such contact by exchanging publications with a number of leading American organizations concerned with planning and public affairs. The growing importance of close and effective relations between Great Britain and the United States demands the extension and encouragement of any means to that end.

The possibility of forecasting the impact of technical inventions on society has been widely discussed, and its many pitfalls have been emphasized repeatedly. The present report, however, while not overlooking these difficulties, distinctly emphasizes the practical possibility of such forecasting and of avoiding many of the most obstinate problems with which their indirect effects have confronted Governments. The impact of inventions never comes instantaneously without signals, and on an average is spread over a period of about thirty years. Moreover, there are three distinct aspects of prediction. It may be possible to forecast in which industries and processes invention is most likely to occur on a considerable scale, which industries are most likely to be affected economically by the impact and what repercussions are most likely elsewhere.

For the technician, the first of these aspects is the most interesting, but for the community, the third and to a lesser extent the second are of more direct and immediate concern. If, however, the work of inventors is to be followed from a broader social and economic point of view, so that opportunities for anticipating and meeting the subsequent repercussions are used, we must have administrators competent to recognize and take account of the scientific and technical factors involved. That this aspect of the impact of invention should be seriously considered is the more important because, as the report indicates, not only is the number of inventions made each year likely to increase rather than to diminish, but also in spite of the difficulty of predicting the effects of specific inventions, it is much easier to forecast the broad social impacts of invention as a whole, since clusters of inventions after all lead to the same social end. For example, the telephone, broadcasting and television all tend to break down individual isolation and privacy, while motor transport, railway electrification, telephones, radio, the cinema and the chain store have all tended to encourage a suburban type of development.

There is, indeed, little information that is new in the present report, but it establishes very clearly the principle that it is a function of Government to watch over and adjust the serious strains and friction which invention may set up in society, while its recommendations for a permanent mechanism for giving effect to this principle deserve study.

In modern industry itself, inventions to-day have four characteristic social tendencies: continuous processes, automatic operation, use of registering devices and use of controlling devices. All of them tend towards the displacement of labour or making a job more mechanical or monotonous, though quite often a few highly skilled or intelligent workers are required as a result in place of many unskilled or manual labourers. Thus, although one result of mechanical invention may be that the more arduous and unpleasant tasks to be performed by manual labour are considerably reduced in number or can be performed by far fewer operators under pleasanter or less exacting conditions, this advantage must be set against the possible effects on displaced workers if no fresh employment is found for them.

Once again, therefore, we are concerned with a net social effect or with the integration of the social consequences of the invention or discovery both direct and indirect. It is precisely such reasons as these which have given a new impetu to social science and research, and to the attemp to plan the utilization of national resources o scientific lines. Moreover, if, as Dr. Ogburn suggests, the lag between invention and its impact o the community makes invention a social barometer it is the more important that every effort shoul be made to read that barometer. It is highl probable, for example, that new developments i industry will threaten the existence of a numbe of skilled occupations, and unless the adoption o fresh methods is carefully adjusted to recruitin policy, and suitable schemes of compensation an retraining for the displaced workers are enforced much friction will result.

The argument for the extension of scientifi planning advanced by this report accordingly rest essentially on human considerations. Scientifi planning as suggested here, the application o scientific methods in an ever-widening field o social and economic problems, is not the handlin of human affairs in the cold dispassionate spher of reason and mechanical efficiency with disregar of human emotions and suffering. On the contrary it seeks to eliminate the selfish direction of industrial undertakings with regard merely to th financial advantage or mechanical efficiency of single enterprise, and to insist that account sha be taken not merely of the well-being of th employees of the concern itself but also of th welfare of the industry and the nation as a whole

The report opens up whole fields of research fo applied psychology, and if it says little or nothin about that aspect of invention which has perhap the first claims on the interest of scientific workers namely, the conditions most conducive to creativ thought and fecund research, its concrete proposals in themselves include some special studie of a few inventions likely to be widely used wit important social consequence. Among these ar the establishment of federal committees on technological unemployment, departmental science committees to investigate and report regularly on th progress and trends of science and invention an their possible social and economic effects, and review of the whole working of the patent laws with a view to adaptation to contemporary needs It is indeed to be hoped that scientific workers an others will be quick to grasp the significance o this report and the challenge it offers to constructive effort no less in Great Britain than i the other English-speaking democracy to which i was primarily addressed.

Procreative Beliefs of the Australian Aborigines

Coming into being among the Australian Aborigines:
a Study of the Procreative Beliefs of the Native Tribes of Australia. By Prof. M. F. Ashley-Montagu. Pp. xxxvi + 362 + 4 plates. (London: George Routledge and Sons, Ltd., 1937.) 21*s*. net.

IN 1899 Spencer and Gillen, writing about the Arunta tribe of Australia, declared that the natives possessed no knowledge whatsoever of the relationship between coitus and pregnancy, and in the early years of this century this gave rise to an extensive controversial literature. Prof. Ashley-Montagu takes up the subject again, and reprints and discusses in his book all the directly relevant records in ethnographical literature. His thesis is "that in Australia, practically universally, according to orthodox belief, pregnancy is regarded as causally unconnected with intercourse". The argument and its conclusion assume a distinction between 'orthodox' belief and what Prof. B. Malinowski in his foreword calls "random statements of irrelevant opinion", but no objective criterion is offered by which to distinguish these different kinds of beliefs. The argument is also vitiated by the fact that the author never makes clear what he means by "causally connected". Thus he accepts (p. 168) the statement of Miss McConnel (which is supported by a myth) that in a Queensland tribe sexual intercourse is regarded as a necessary condition of conception, and then writes, "the important point of course here is that these natives do not regard intercourse as the cause of conception but only as a condition thereof". Since for the modern scientific investigator coitus is a necessary but not a sufficient condition of pregnancy it is difficult to understand what is the nature of that "causal connection" of which the Australians are said to be ignorant. But the author is not consistent, since (on p. 237) he says that for the Australian native sexual intercourse "positively has no connection with childbirth".

There is good evidence from recent field-work that in a number of Australian tribes there is a recognition of some connexion between sexual intercourse and childbirth. Most of the work during the last ten years has been carried out in the northern part of the continent, since it is there that are to be found the tribes that have not been destroyed by white invasion. Prof. Ashley-Montagu, in order to maintain his thesis, treats these tribes as "aberrant" and writes: "there is every reason to believe that the beliefs of the tribes in this general region are not strictly indigenous, that there is some evidence that they are of foreign origin, and that for this reason they cannot be regarded as strictly aboriginal Australian beliefs" (p. 113). But he adduces nothing that can properly be regarded as evidence for this view.

Another weakness of the argument is that the author, as he himself notes, takes the Arunta of the Alice Springs district as typical of the whole of Australia. What is typical of Australian tribes taken together is not anything found in any one particular tribe, but those general characteristics which are common to all or to the great majority. The Arunta have their own special beliefs about childbirth which are not shared by the majority of Australian tribes, and to take these as typical of the continent is invalid.

The author assumes that in their beliefs, or rather in their 'orthodox' beliefs, the Australian natives are logical and consistent. ("In his own thought the savage is perfectly logical", p. 340.) When, therefore, he finds in the accounts given of the beliefs of any tribe, things that seem to him inconsistent, he falls back on the distinction between 'orthodox' and other beliefs, or else treats the inconsistencies as if they arose, not from the statements of the natives themselves, but from the way in which they are reported by the ethnographer.

There doubtless is a certain kind and degree of consistency among the Australian beliefs, but it is not of the kind that the author has in mind. Many Australian tribes hold a belief that a woman becomes pregnant because a "spirit-child", as the native term is often translated, has entered into her. Prof. Ashley-Montagu accepts this as the 'orthodox' belief, and seems to think that people who hold it cannot also recognize any connexion between pregnancy and coitus. If we had no more knowledge about the beliefs of Roman Catholics than we have about those of the Australian aborigines, we should, by following the author's methods, conclude that the orthodox belief that every child born into the world is the result of a special act of creation by God is incompatible with the belief that the child results from the fertilization of an ovum by a spermatozoon. But we do in this instance know that the two beliefs are held together and are made consistent by the distinction between soul and body.

The dangerous unsoundness of Prof. Ashley-Montagu's simplistic, almost naïve, treatment of the Australian problem may be illustrated by yet another instance from our own society. Anyone in modern Europe who believes that the human soul continues to exist after the death and dissolution of the body will be likely on certain occasions to deny that thought and feeling are dependent on physiological processes in the nervous system, yet will also on occasions recognize that it is through such physiological action that unconsciousness results from chloroform or a blow on the head. An inquiring anthropologist from another world using Prof. Ashley-Montagu's methods would conclude that in twentieth century England, according to orthodox belief, conscious thought is regarded as causally unconnected with the physiological functioning of the brain.

In Australian tribes the phenomena of pregnancy and childbirth are associated with a number of things, with menstruation and with menstrual blood and thereby with the moon, with the small whirlwinds that swirl across the country in hot weather, with rain as the primary source of fertility in Nature and with the rainbow-serpent in which the life-giving power of water is personified, with food, with dreams, with the totemic ancestors, with certain sacred spots (baby totem centres) at which members of the baby totem group perform ceremonies to produce a supply of babies in the tribe just as members of the kangaroo totem by similar ceremonies multiply the kangaroo. Many of these ideas are found associated together in a single tribe. They afford a means by which the Australian aborigines represent to themselves the place of childbirth in a complex order which is at one and the same time the social order and the natural order. In spite of the author's attempts to explain it away, there is clear evidence that in many tribes there is included in this set of ideas an association between childbirth and sexual intercourse. The anthropologist who knows his business is not disconcerted when he is told by the same informants that babies come from the moon, that pregnancy results from a woman eating food which makes her sick, that there would be no children if there was no copulation, and that to ensure a proper supply of babies it is necessary once a year to perform a ceremony at the baby totem centre. What is needed in a scientific treatment is an examination of what these associated ideas mean in the thinking and the behaviour of the natives themselves, not a discussion of them in terms of our own complex notion of efficient causation, which is a product of centuries of Aristotelian philosophy and of scientific and technological development. What consistencies and inconsistencies there are must also be studied in the minds of the natives themselves, not in terms of our own conceptions. To such a needed study the book under review makes no contribution of any value.

To his thesis that the Australian aborigines are ignorant of physiological paternity the author adds, in his thirteenth chapter, the thesis that they are also ignorant of "physiological maternity". What exactly he means by the latter thesis is even more obscure than what he means by the former. The writing throughout the book is awkward, and there are occasional faults of grammar. The map on p. 292 showing the distribution of subincision, taken from Basedow, is incorrect. There seem to be very few misprints; a line of type, seven from the bottom, has been dropped on page 260. The reviewer is unable to agree with the lavish, even extravagant, praise that is bestowed on the work by Prof. B. Malinowski in his foreword.

A. R. RADCLIFFE-BROWN.

The Newer Outlook on Animal Nutrition

Animal Nutrition
By Prof. Leonard A. Maynard. (McGraw-Hill Publications in the Agricultural Sciences.) Pp. xiv + 483. (New York and London: McGraw-Hill Book Co. Inc., 1937.) 24*s*.

AS the modern system of intensive production, calling for higher and higher milk yields or rapidity of growth, has developed, so not only have the demands of the animal for quantity of food increased, but also many new requirements as to the quality of the feed have been set up. Attention has therefore to be focused on special nutritive requirements previously unrecognized. It is especially in this respect that the book under notice extends the older works on animal nutrition.

Although the book is written primarily with application to farm animals, it does not deal with detailed feeding practices, as are already to be found in other books, but rather it seeks to show how the newer outlook on animal nutrition can assist these practices.

The subject is treated from the wide point of view of the comparative physiologist, both in obtaining general principles by a comparison of species and in the application of those principles to different species. This wider point of view is also seen in the chapters on growth, reproduction and lactation, in which the special nutritive requirements of these functions are considered in detail. Problems of intermediary metabolism and the means by which the nutriment in the body is regulated to the different organs are involved.

The inorganic elements and the vitamins required by the body are treated at length, particularly in relation to deficiency diseases and to questions of improved health and efficiency in different species of animals. Several sections are devoted to the technical side of running nutritional experiments, such as the determination of digestibility, nutritional balances and respiration calorimeters, while others deal with some of the physico-chemical bases of the life-processes, such as the absorption of radiation.

Interesting accounts of recent work on various points of practical interest at the present time include such problems as the storage of iron by the fœtus during pregnancy in its connexion with the study of anæmia, the nutriments required for egg production, the effects of the method of preservation of greenstuffs on their vitamin content, the relation of food fat to depot fat, the role of water in the body, and particularly the experiments quoted on the effect of improvements in the nutritional regime in causing better physical development in animals and man.

As the book throughout contains references to the literature, often from reports of agricultural experiment stations and other scattered sources, it should prove very useful to those engaged in nutritional work. Brief historical accounts of noted names in nutritional science are given in footnotes.
J. H.

Biological Positivism

The Axiomatic Method in Biology
By Dr. J. H. Woodger. With Appendices by Alfred Tarski and W. F. Floyd. Pp. x + 174. (Cambridge: At the University Press, 1937.) 12*s*. 6*d*. net.

DR. WOODGER'S book is an attempt to do for a part of biology what Whitehead and Russell, in "Principia Mathematica", did for mathematics. Starting from as small a number as possible of axioms and undefined terms, he proposes to deduce known biological generalizations, and to discover new ones by pure deduction. For this purpose he uses a special set of symbols, including many taken from Whitehead and Russell, and 125 new ones. Some of these, for example, **cell**, are undefined, whilst others, for example, **Ps**, meaning the relation of sexual parenthood, are defined in terms of cell lineages.

The author then arrives at a quasi-mathematics in which the fundamental operations are the division and fusion of cells, and the division of cell-parts, for example, genes. If any system conforms with his axioms, the theorems deduced will be true for it. Some of these theorems are applicable to taxonomy, some to embryology, but the majority to genetics. In this latter field, at any rate, Dr. Woodger's method is unsuited to deducing new results. Thus on p. 114 we are presented with an "unsolved problem", the solution of which can, however, be written down without difficulty by anyone familiar with Wright's mathematical methods.

This might not matter if the axioms used in deduction were biologically as well as logically correct. But they are not. Thus, on p. 70, **g** (for gamete) is defined as the class of cells which fuse in pairs to form a zygote (according to a restricted definition given earlier). Now a female cell which fuses with a male gamete may be a haploid (as in higher plants) or a diploid which only extrudes its second polar body after fertilization. Here an attempt to define gametes exclusively in terms of cell divisions and fusions leads to the loss of the fundamental distinction between diploid and haploid cells.

Again, on p. 92 in the definition of a "continuous component" of a cell series, it is apparently assumed that genes and chromosomes do not divide during the first meiotic division, which is therefore always reductional. This is known to be untrue. Hence not only is the whole subsequent genetical theory only proved for a non-existent class of organisms, but also any treatment of segregation in *Ascomycetes* becomes impossible.

It is perfectly true that both these mistakes occur in text-books of biology. But if Dr. Woodger's method is to be justified, it can only be on the ground of greater accuracy and rigour than are to be met with in current biological writing.

I believe that these errors arise from an attempt to be positivistic rather than materialistic. If we attempt, out of the inconceivable richness of biology, to concentrate on a few characters or processes which lend themselves readily to abstract description, we inevitably lose sight of biological realities. A classical example is the Linnæan system of flowering plants, logically perfect, but often at variance with the natural system based on community of descent.

In my own opinion, the attempt to fit the facts of life into any logistic scheme is likely, in the long run, to be a failure. But it will be a useful failure if it serves to show up false assumptions which we tacitly make. Some, such as the existence of female gametes, are relatively trivial. Others are much more deeply involved in our thought, and if they are false the results are much more serious.

Thus, Dr. Woodger assumes that a cell can be divided into momentary parts, that is to say that in theory, at least, we can specify the state of a cell at any instant with no limit to our accuracy. This is untrue for an atom, and, if it is correct that change is part of the very essence of life, it may turn out to be even more glaringly untrue of the cell.

Again, it is assumed that certain cell-parts, for example, genes, are individuals each with one and only one ancestor at any past date. This assumption has so far satisfied geneticists. But actually when two like genes come together in a homozygote at pachytene, and after a time which may be as long as forty-five years, finally separate, it is impossible to say which of the separating genes represents a given one of the synapsing genes. The uncertainty may be small, but is not necessarily negligible, and may prove very important.

Similarly, it is assumed that genes divide. This may be true. It is equally plausible that they reproduce by copying rather than by division.

The value of Dr. Woodger's book will be greatly enhanced if he clears it, so far as possible, both from definite myths, such as that of the female gamete, and from postulations of unobserved phenomena, such as gene division. If this is done, his method may prove valuable for morphologists for some generations to come, although until it takes cognizance of chemical facts it will be of little use to the biologist and none to the biochemist. But at present it falls between the two stools of positivistic description and materialistic explanation. I believe that the former ideal is in the long run unattainable. But the attempt to attain it has inspired such biologically valuable work as that of Karl Pearson.

In his preface Dr. Woodger emphasizes the tentative character of his book. If it proves possible to rewrite it in terms of observable phenomena only, without such postulates as gene divisions and momentary states of cells, it will be a valuable contribution to human thought. Until then, its main importance may be to lay bare erroneous assumptions rather than to serve as the basis of a further theoretical construction. J. B. S. HALDANE.

Synaptic Transmission

Autonomic Neuro-Effector Systems

By Prof. Walter B. Cannon and Prof. Arturo Rosenblueth. (Experimental Biology Series.) Pp. xiv + 229. (New York: The Macmillan Co., 1937.) 17*s.* net.

SEVERAL reviews have been written recently dealing with the chemical transmission of nervous impulses. A monograph has now been published which gives, for the first time, an authoritative exposition of the views of the Harvard School. The authors have both written many papers describing investigations of the properties of adrenergic nerves. They have shown that stimulation of these nerves causes the liberation of at least two different substances. The clear presentation of the evidence for this conclusion forms the most valuable and impressive feature of the book. No one could question the experimental results, but their interpretation is still in doubt. The theory that drugs combine with a special receptive substance in the motor organ provides the only reasonable explanation of the specificity of drug action, but Cannon and Rosenblueth's theory that this receptive substance is liberated with the drug into the blood stream seems unnecessarily complicated, and has met with opposition.

The book is argumentative. The authors reject Bacq's rather factious criticisms of their theory of sympathins *E* and *I*. They reject the theory advanced by Monnier and Bacq to account for the failure of 933*F* to antagonize the effect of adrenergic nerves in favour of that advanced by Dale and Gaddum to account for similar phenomena in connexion with atropine. They reject the theory which explains dose-effect curves in terms of individual variations of the sensitivity of muscle elements on the ground that it would be necessary to assume that the logarithm of the sensitivity of these elements was normally distributed. This is not the weak point of the theory in question, since the logarithms of biological quantities usually *are* normally distributed. They accept the theory which regards these curves as hyperbolæ, and interprets them in terms of mass action, but do not appear to realize that, on this theory, the ratio to one another of the potency of two solutions must be independent of the size of the doses used.

This book is, in fact, likely to lead to much discussion. J. H. G.

The Camford Visitation

By H. G. Wells. Pp. 76. (London: Methuen and Co., Ltd., 1937.) 2*s*.

MR. WELLS'S address as president of the Educational Science Section of the British Association last year dealt with certain aspects of education in the schools only. In his latest story, with its cover of dark and light blue, he deals with university education and its place in society. The story begins with an amusing sketch of a dyed-in-the-wool scholar, the master of Holy Innocents College, a preserver of culture, of true scholarship, born to appreciate without ever creating. His breakfast oration has got to the stage of denouncing "the dictatorship of the half-educated. . . . We are being endowed, Sir, and told what to know and teach, by the unholy wealth of ironmongers and the overblown profits of syndicated shop-keepers." Then enters the visitant as a voice, an unseen presence, asking: "Half-educated? Now how can you measure education and divide it into halves and quarters? What do you *mean* by education? . . ." For the rest of the story the visitant subjects human life, and in particular its treatment by the University of Camford, to a sympathetic but quite unsparing scrutiny. The general thesis is an appeal to the universities to play a part in "so heroic an ordering of knowledge, so valiant a beating out of opinions, such a refreshment of teaching and such an organization of brains as will constitute a real and living world university, head, eyes and purpose for Man".

In the development of the thesis many topics are reviewed or touched, with Wellsian incisiveness and ironic humour—the claim that the humanities are wisdom and that science is not, the pseudo-scientific explanations of psycho-analysis, the fashionable philosophy-cum-politics-cum-religion called dialectical materialism. "To see a novel proposition pass through a Marxist gathering is like watching a breeze across a field of ripe corn. It passes, and the serried minds return to their upstanding integrity." Mr. Wells is here as stimulating, provocative and entertaining as ever, but the visitant treats university science teaching more kindly than we should have expected.

Out of my Life and Work

By Auguste Forel. Translated by Bernard Miall. Pp. 352+8 plates. (London: George Allen and Unwin, Ltd., 1937.) 16*s*. net.

THIS volume of memoirs deals with a full and varied life. Prof. Forel became a psychiatrist by profession and simultaneously was one of the leading European myrmeologists. A narrow and isolated early upbringing led him to take refuge in Nature around him and, before he was eight years old, he had become interested in ant life. Forel was destined for medicine, and he seems to have prosecuted his studies in this subject side by side with those on ants. Failure to pass the examinations at Zurich led to his transference to Vienna. Here he graduated and secured his first post, which was under Prof. Gudden in Munich.

Forel had been working for some time at his "Ants of Switzerland" and in 1875 this treatise received the Thore Prize of the Paris Academy of Sciences. In 1879 he became assistant physician at the Burghölzli Asylum, overlooking Lake Zurich. Here he remained for nearly twenty years, becoming its director, and also professor in the University of Zurich. His energies were devoted to research, teaching and treatment in connexion with insanity. His earlier studies on the brains of normal individuals and of mental deficients were followed by his development and application of hypnotic suggestion as a method of treatment. He tells much of his life at Burghölzli, of its trials, misunderstandings and successes; of his travels to other lands in order to further his studies of ants; of his politics and of his efforts as an uncompromising opponent of alcoholism; and of his life in retirement and its retrospection. These memories are written in a frank, unpretentious style, and reflect their author's efforts in recording the events of his life in their proper perspective. The work of translation has been ably done by Mr. Bernard Miall.

The Chromosomes

By M. J. D. White. (Methuen's Monographs on Biological Subjects.) Pp. viii+128. (London: Methuen and Co., Ltd., 1937.) 3*s*. 6*d*. net.

THIS competent book of 128 pages provides a guide to recent discoveries in cytology. It describes the phenomena of mitosis and meiosis, considers chromosomes in relation to evolution and does not shrink from invading the realms of advanced cytological theory. The book contains a curious mixture of well-written, easily understood remarks on advanced work, combined with involved descriptions of more elementary material. This is probably due to the author's endeavour to cover as much of the ground as possible in a small book.

A glossary is provided, but the definitions are not always strictly specific. The book is to be recommended to those who require a summary of the modern theories and discoveries of cytology and will undertake further reading of authorities in the excellent bibliography. F. W. S.

Life and Death:

the Autobiography of a Surgeon. By Prof. Andrea Majocchi. Translated by H. J. Stenning. Pp. 343. (London: George Allen and Unwin, Ltd., 1937.) 10*s*. 6*d*. net.

THE author of this temperamental book, which is obviously intended as much for the layman as for the medical reader, is professor of surgery at Milan and consultant to the Ospedale Maggiore. In addition to a short history of this hospital, the work contains a vivid description of the author's practice in the Obstetrical Department, his visits to the surgical clinics of Switzerland, the United States, Paris and Berlin, his War service at the Front and especially the treatment of wounds of the abdomen, brain and spinal cord and the "roses and thorns" of a surgeon's career. Chapters are also devoted to the nursing profession as seen through Italian spectacles, and a satirical account of a medical congress.

Soil Conservation in Tropical Africa

By Dr. L. Dudley Stamp, director of the Land Utilisation Survey of Britain

THE attention which has recently been given to the widespread and serious nature of soil erosion in the African continent has perhaps insufficiently emphasized two aspects of the problem. One is that the serious and rapid erosion is of recent growth—not only in large measure consequent upon the control of the continent by Europeans but also actually in danger of being increased by the very measures designed to combat it. The other is that the African cultivator has already evolved over large areas a system of farming designed to combat soil erosion and maintain soil fertility, and that the essential need is to encourage and develop this system rather than to supersede it. A recent tour in Nigeria has convinced me that the African system may hold the key to the solution of some of the most urgent problems of soil erosion in America and elsewhere.

Prior to the European partition of tropical Africa, internecine strife and the incidence of disease, both epidemic and otherwise, resulted naturally in a limitation of population and of any serious pressure on the land in purely agricultural areas, and prevented overstocking both by man and by animals on grazing land. Nowadays, population density in parts of Southern Nigeria reaches more than five hundred to the square mile, whilst the number of cattle in Kenya increased from three to six million between 1920 and 1936.

In Southern Nigeria, a land of adequate rainfall (60 to 150 inches or more), naturally clothed with high forest but where certainly less than one per cent of virgin forest remains, the land is divided up between the village communities. Each village tract—in other lands one would say parish—is held communally and farmed on a well-marked system of rotation, each family returning in the appropriate year to farm its own special portion. The system is often, though wrongly, referred to as 'shifting cultivation', and has even by foresters been called after the system of temporary mountain clearings in Burma a 'Taung-ya' system, which it certainly is not. It is best described as 'bush-fallowing', a period of cultivation being followed by a long period of fallow, the only difference from the fallows of temperate lands being that the forest trees form the 'weeds' of the fallows. Seven to ten years (during which the trees grow to thirty feet in height) may be regarded as the normal period of fallow; it is when the pressure on the land is such that the fallow period has to be reduced perhaps even to as little as two years that the system breaks down. When the time comes, the fallow is cleared by burning—better if the burning is as early as possible after the rains so that the fires are not so fierce as to destroy the valued oil palms or completely to destroy the vitality of the stumps left in the ground.

Southern Nigeria is mainly tsetse infested: cattle are entirely absent over large areas and cultivation is entirely by hand—by the hoe. A family can cultivate two or three acres in this way and produce an adequate supply of the staple food—yams—together with limited quantities of cassava (manioc), corn (maize) and a supply of vegetables in the little garden plot (permanently cultivated) round the hut itself. Thus at any given time the village tract appears to be a series of tiny patches of cultivation in the midst of ragged, untidy second-growth forest of varied age. The patches themselves are a series of mounds or of yam hills (in which the yams or cassava are planted), a few stalks of maize or a few beans or gourds growing in the intervening hollows, and stumps of trees still remaining. Weeds are by no means absent, but the soil is protected. If some of the finer fractions are washed out, they are held up by the neighbouring tract of woodland. If Western ideals of ploughing, extensive clearing, weeding and single cropping were introduced, the soil would immediately be subject to serious erosion from which it is at the moment free. The Agricultural Department in Nigeria has rightly recognized this, and is concentrating its attention on the improvement of the present system by green manuring (by leguminous crops) to replace *part* of the fallow, early burning to prevent serious destruction by fire, and the improvement in quality and yield of the crops grown—especially those which may serve as additional cash crops (citrus, cocoa, oil palm, cotton, kola nuts, etc.) and supply the African with the money he needs for taxes, bicycles, travelling, clothing and the various demands coincident with an increased standard of living.

Northern Nigeria consists of large emirates in which the emir holds the land in trust for his people. The cultivators are his tenants, though often holding the land indirectly through the district headmen. The rainfall ranges from about 25 inches along the northern border to 60 inches in the south, and comes essentially in the wet

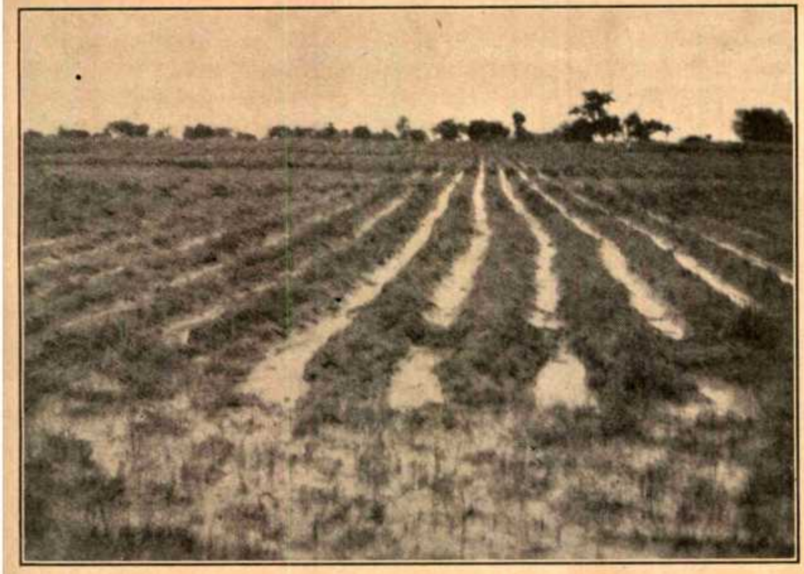

Fig. 1.

THE INTRODUCTION OF THE PLOUGH IS LIKELY TO CAUSE EROSION OF THIS TYPE (KANO, NORTHERN NIGERIA). AFTER A HEAVY RAINSTORM, EACH FURROW HAS BECOME AN EROSION CHANNEL CARRYING OFF THE LIGHTER, VALUABLE FRACTION OF THE SOIL.

season from April until October. It falls generally in a succession of storms, four inches in a single night being by no means unusual, and in consequence the predominantly light sandy soils are particularly liable to both sheet and gully erosion. In the dry season the country is parched and bare, and liable, at least in the north, to considerable wind erosion from the dust-laden Harmattan, though the film of fine dust which this wind from the Sahara deposits is not without its value to the soil. The population of the Northern Provinces is irregularly distributed —largely influenced by water supply, with the result that the Geological Survey is at present very actively engaged in well-siting and well-sinking. There is still a sharp distinction between the nomadic, or semi-nomadic cattle-rearing Fulani and the settled Hausa cultivators, though the latter are not blind to the value of manure and may even hire the large white-humped zebu cattle from the Fulani for the sake of their droppings.

The natural vegetation of the Northern Provinces is an open savannah forest with an undergrowth of grass, merging northwards into acacia scrub woodland. Uncontrolled grazing by cattle and the large northern goat results in an uneconomic use of the land, of which there would be ample for normal cultivation on the same basis as in the south. Hence it is, very rightly, the policy of the Agricultural Department to introduce and popularize by means of a series of demonstration farms a system of mixed farming, and to fuse the diverse interests in the land of the Fulani and Hausas. The results are gratifying. In 1928 three farmers tried the experiment; by the end of 1934 the number had increased to 298, but in the next year it had leapt to 621. The staple food crops of the north are the tall guinea corn (with stalks valued for roofing and light fencing), other millets (with a less valuable straw), together with some maize, cassava, and a few yams and, locally, rice. The staple cash crops are ground nuts and cotton. The traditional agricultural implement is the hoe, by which a family cultivates about three acres. The Agricultural Department has introduced a light plough throwing up a ridge on either side and which is to be drawn by the cattle now to be kept penned with millet straw bedding (making a manure with binding qualities on the light soils).

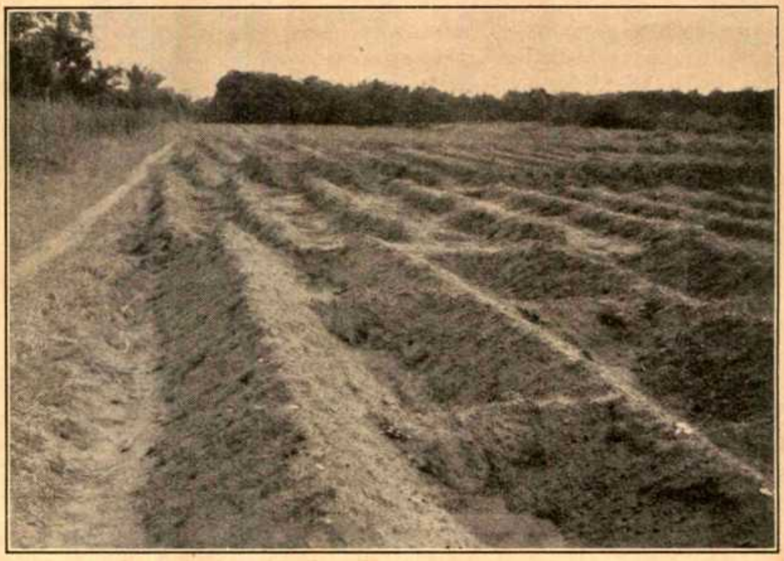

Fig. 2.

THE 'RIDGE AND BASIN' SYSTEM OF NATIVE CULTIVATION IN NIGERIA. THE METHOD IS VERY EFFECTIVE IN PREVENTING SOIL EROSION; THE RAIN WATER ACCUMULATES IN THE BASINS AND SEEPS GRADUALLY AWAY.

The donkeys and goats, so universal in the north, are similarly to be penned and manure prepared in the same way. On this system a family can easily farm twelve acres.

A visit to the experimental farm near Kano, which fortunately took place after nearly four inches of rain had fallen during the night, convinced me that the introduction of the plough into the light land of northern Nigeria is liable to prove a curse which will more than outweigh the blessing conferred by mixed farming. Every furrow is a water course taking off the needed water, every one an incipient erosion gully (Fig. 1). Cross-ploughing at intervals is not a remedy—a new gully is formed—nor is contour ploughing in this gently undulating plain land sufficient.

Fortunately the local cultivator has already evolved a system which points the way. Instead of the yam hills of the south are ridges (from three to six feet apart and from nine inches to thirty inches high) crossed at intervals by ridges at right angles. Instead of the long straight plough-furrow the result is a series of isolated basins. Into these are swept the finer particles of soil during a storm but no soil is lost, for the basins fill with water, which later seeps away. Only rarely does a ridge give way, and even so it is easily repaired. When the land is prepared for the next year's crop the new ridge takes the place of the previous hollow, so that the soil is well mixed again (Fig. 2). The same result can be achieved by ploughing, if the plough is lifted at intervals. This can readily be done with the light plough used. It is clear that the careful use of cover-crops (a dirty farm is probably better than a well-weeded one), the restoration of fertility by leguminous crops, and the maintenance of wind breaks or 'protection forests' (the Forestry Department in conjunction with the French authorities are to preserve the remaining tracts of scrub and woodland along the international border) are all necessary in addition, as well as the control of areas where erosion is already serious.

If America could invent a plough which will imitate the Nigerian system by replacing the long furrow by a series of isolated elongated basins, one at least of her major problems in the dry lands of the Middle West might be solved.

Observations made in the Highest Stratosphere Flight

A DETAILED account has been published* of the scientific results of the flight of *Explorer II*, in which, on November 11, 1935, Major A. W. Stevens and Captain O. A. Anderson ascended to a height of 72,395 feet, or 12·7 miles. This is the greatest height ever reached by man.

To prevent any possibility of a repetition of the disastrous explosion which occurred during the descent of *Explorer I*, it was decided to fill *Explorer II* with helium, even although this meant making the balloon considerably larger. The difficulties of filling these huge balloons are very considerable, and the most suitable place that could be found for carrying out this operation was the "Stratosphere Bowl", a natural crater in South Dakota providing complete shelter from the wind. It was intended to make the ascent in June, but when the balloon was half full the fabric burst round the 'rip-panel'. This panel was to be used for rapid deflation when the balloon landed. As a result of this mishap, the balloon had to be considerably modified and was not ready until October, and suitable weather for the ascent did not occur until November.

A great many people co-operated to make this flight a success. Measurements were made of the angular distribution of cosmic rays, and the nature of the corpuscles forming them, the distribution of ozone, the conductivity and constitution of the air in the stratosphere, and of the intensity of solar and terrestrial radiation. It was proved that the spores of certain moulds and bacteria can and do exist in the stratosphere, and an attempt was made with rather inconclusive results to find whether the great intensity of cosmic radiation would accelerate mutation in *Drosophila*.

Cosmic Rays

The cosmic ray measurements were for the most part carried out under the direction of G. F. Swann. For measuring the angular distribution of cosmic rays a battery of ten cosmic ray telescopes and 210 Geiger counters were used. Five of the telescopes were shielded with lead. The results of this work are illustrated in Fig. 1. In the case of the vertical telescopes, maxima were obtained at the heights corresponding to one and two metres of water below the top of the atmosphere respectively, but these maxima were less pronounced at greater zenith angles. The existence of a maximum in the ionization-depth curve shows that it is secondary and not primary particles which do most of the ionizing, and the depth of the maximum gives a measure of the range of these particles. The cause of the second maximum is rather obscure.

---

* "The National Geographic Society—U.S. Army Air Corps Stratosphere Flight of 1935 in the Balloon 'Explorer II'." (Contributed Technical Papers, Stratosphere Series, No. 2.) (Washington: National Geographic Society, 1936.)

It was unfortunately considered impracticable to take cloud chamber photographs of cosmic rays although a special chamber was ready to be taken up. This seems a great pity and in the opinion of the reviewer more useful information would have been obtained by taking up a cloud chamber than a wireless transmitting set. Instead, the balloon carried a number of photographic plates specially prepared with pinacryptol yellow. Such plates serve as continuously acting cloud chambers, in that ionizing particles leave characteristic tracks when the plates are developed; moreover, by counting the grain spacing under a microscope, it is possible to distinguish the track of a proton from that of a heavier particle. The plates were packed in flat nitrogen-filled rubber bags, and some of them were placed almost in contact with compounds of different elements so that the effect of bombardment of these elements by cosmic ray particles could be observed. Locker and Rumbaugh concluded that α-particles form at most a fraction of 1 per cent of the ionizing particles. The neutron intensity at an equivalent of half a metre of water is more than 2,000 times as great as at six metres, and at this height they form a considerable proportion of the ionizing particles although they carry less than 2 per cent of the energy. The rest of the energy must be carried by photons, positrons and electrons, which cannot be detected by this means.

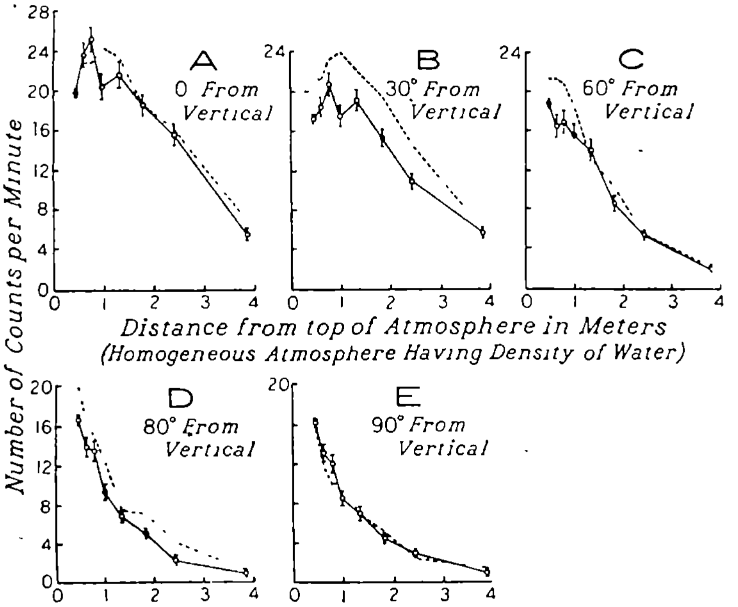

Fig. 1.

IONIZATION-DEPTH CURVES. THE FULL LINES REFER TO SHIELDED, THE DOTTED LINES TO UNSHIELDED, COUNTERS.

The technique which has been evolved for using photographic plates as continuously acting cloud chambers should prove very valuable and, as there is no need to have a manned balloon to carry the plates into the stratosphere, it is to be hoped that this work will be continued with unmanned balloons.

OZONE

The ozone measurements were made with an ultra-violet spectroscope developed by O'Brian, the amount of ozone between the observer and the sun being deduced from the absorption of the ultra-violet rays. As it was not possible to keep the instrument pointed directly at the sun, sunlight was scattered into the instrument by a diffusing sphere. This also scattered sky light into the instrument, but the effect of this seems to have been neglected. A second instrument was carried to make spectrograms of the sky 9° above the horizon, and with this it was hoped to deduce the distribution of ozone above the balloon, although it is not very clear how O'Brian intended to do this. The second instrument might have been better employed on the ground to measure the changes in the total amount of ozone during the flight.

It is evident from Fig. 2 that the distribution of ozone found by O'Brian on the flights of *Explorer I* and *II* do not agree well with those found by Regener with unmanned balloons, nor with those found by Götz, Meetham and Dobson at Arosa from measurements on the ultra-violet spectrum of the zenith sky at sunset. His distribution agrees more closely with those found by Meetham at Tromsø in latitude 69° 40′ than that at Arosa, which is at about the same latitude, namely, 40°. There was little ozone near the ground or below 15 km., and the maximum concentration was at 22 km., almost exactly the height reached by the balloon. The other workers found much larger concentrations near the ground.

CONDUCTIVITY

Knowledge of the electrical conductivity of the atmosphere in fine weather is of great importance as it enables us to find the potential of the Heaviside layer. If we assume that the vertical air-earth current is constant and equal to i units per sq. cm., then if λ is the total conductivity (equal to the sum $\lambda_+ + \lambda_-$), the potential is $i\int_0^H \frac{dz}{\lambda}$.

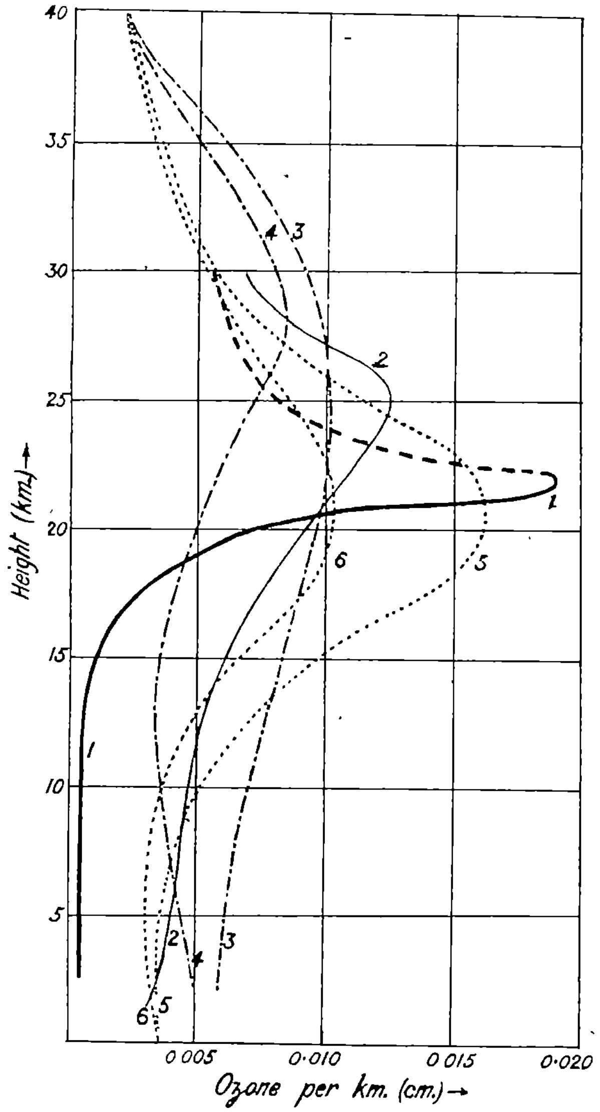

Fig. 2.

Ozone per kilometre as a function of altitude.

Curve 1. Flight of *Explorer II*. Total ozone. $x = 0 \cdot 19$ cm. Dotted part derived from sky observations.

Curve 2. Regener's sounding balloon. $x = 0 \cdot 28$ cm.

Curves 3 and 4. Ground determinations by Gotz, Meetham and Dobson at Arosa. Curve 3: $x = 0 \cdot 20$ cm. Curve 4: $x = 0 \cdot 30$ cm.

Curves 5 and 6: Ground determinations by Meetham at Tromsø. Curve 5: $x = 0 \cdot 30$ cm. Curve 6: $x = 0 \cdot 22$ cm.

Regener and others have measured the ionizing power of cosmic rays at different heights at the same latitude as Dakota; making certain assumptions and neglecting the effect of nuclei of condensation, the positive conductivity should be

$$\lambda_+ = 9{\cdot}8 \times 10^{-6}\frac{T^{5/3}}{p}I^{\frac{1}{2}}.$$

It is of great interest to compare this value with a direct determination.

Gish and Sherman constructed a rather ingenious modification of Gerdien's apparatus for measuring the conductivity. It consisted of a charged insulated rod in a cylindrical condenser through which air was aspirated. When the rod had lost a certain charge and therefore reached a critical potential, it was automatically recharged and a mark was made on a spiral record. By means of switches the potential to which the rod was charged could be made positive or negative and could be given various values, so that the same apparatus could be used for measuring positive and negative conductivities at several sensitivities.

The air conductivity was enormously greater at high altitudes than near the ground, but at all altitudes the positive and negative conductivities were in the constant ratio 0·78. This is not in agreement with laboratory experiments, but these are probably vitiated by free electrons. The conductivity on the descent was less than that on the ascent, but the authors believe that on the ascent the air was contaminated by gases from the balloon.

The conductivity was not equal to $9{\cdot}8 \times 10^{-6}\frac{T^{5/3}}{p}I^{\frac{1}{2}}$, but it can be seen from Fig. 3 that from 3 km. to 18 km. it agreed very well with the formula

$$\lambda_+ = 9{\cdot}8 \times 10^{-6}\frac{T^{5/3}}{p}I^{\frac{1}{2}}.\left(\frac{p}{p_0}\right)^{0\cdot36}$$

where p_0 is the pressure on the ground.

Below 3 km. divergence from this value was to be expected because of the presence of nuclei of condensation. The authors suggest that the discrepancy above 18 km. was either due to the fact that the air was not drawn sufficiently fast through the Gerdien condenser, or to the presence of more nuclei. Some support to the latter hypothesis is provided by the fact that a new air mass was encountered at about this height. That there can be nuclei of condensation in the stratosphere is proved by the occasional occurrence of mother of pearl clouds at 18–30 km.

It is very much to be hoped that this work will be followed by further experiments with unmanned balloons. In any event Gish and Sherman are to be congratulated on a very valuable piece of work. They deduce a potential for the Heaviside layer of about 400,000 volts.

AIR COMPOSITION

In the troposphere, the air is being constantly mixed, and has almost perfectly uniform composition except with regard to water vapour and carbon dioxide. The great stability of air in the stratosphere to be expected from the absence of temperature gradient led people to expect that in this region each gas would behave independently of the others, so that there should be an increasing preponderance of light gases at great heights, for example, hydrogen and helium. However, the behaviour of balloons in the stratosphere has shown the existence of considerable winds giving rise to mixing; the extent to which this mixing is complete is of considerable interest to the geophysicist.

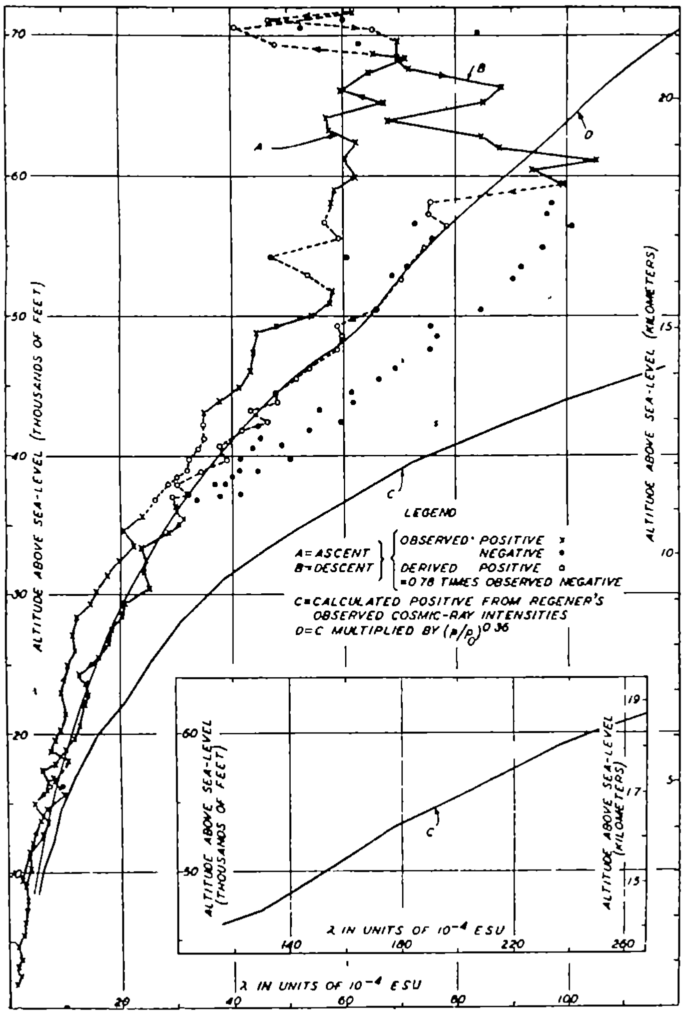

Fig. 3.

AIR CONDUCTIVITY, FLIGHT OF *Explorer II* NEAR RAPID CITY, SOUTH DAKOTA, NOVEMBER 11, 1935.

Various methods have been devised by which samples can be taken with unmanned balloons, and in England a good deal of work of this nature has been done by Paneth and Dines; with small sounding balloons, however, it is difficult to get large enough samples for very accurate analyses. *Explorer II* carried up three flasks, all of which were exposed at about 21·5 km., just at the beginning of the descent. The third of these had a very ingenious valve for admitting air, but unfortunately this failed owing to the presence of a drop of oil in a capillary tube.

Paneth has shown that helium provides the best criterion of mixing, since the amount of hydrogen is everywhere negligible, and helium is the next lightest gas. The two samples were analysed for helium, oxygen and carbon dioxide, the former by measuring the residue when the other gases were absorbed in charcoal. The amount of helium was about fifty times what was to be expected, but this only shows that the air was contaminated by helium from the balloon.

Oxygen was determined both by absorption in potassium pyrogallate and by combustion with hydrogen. The two methods agreed well, and the final results were:

Carbon dioxide	0·029 ± 0·002
Oxygen	20·895 ± 0·003

At ground-level the proportion of oxygen is 20·945 per cent. The authors are uncertain whether the difference can be regarded as representative or whether under the peculiar weather conditions of the flight the air which they sampled was not brought down from even greater heights.

MICRO-ORGANISMS

Rogers and Meier performed experiments to determine whether there are any spores present in the stratosphere. It is well known that these can withstand great extremes of cold; their presence in the stratosphere would throw much light on the spread of micro-organisms, and would also demonstrate the mixing between stratosphere and troposphere air.

A special spore-collecting apparatus was devised which was dropped from the stratostat at 71,000 feet. It was carried down by a parachute which would open some time after leaving the balloon. As soon as the parachute opened the collector was exposed. It was afterwards closed by syphon bellows at 36,000 ft., which is just about the height of the base of the stratosphere.

Every precaution was taken to avoid contamination, and on incubation on agar jelly at 30° C. five colonies of bacteria and five moulds developed. The bacteria were all different and afterwards withstood temperatures much lower than those encountered on the stratosphere flight. The moulds were identified as *Rhizopus*, *Aspergillus niger*, *Aspergillus fumigatus*, *Penicillium cyclopium* and *Macrosporium tenuis*, all of which have frequently been collected on aeroplane flights.

CONCLUSION

A considerable amount of very useful data was obtained on this flight, and one has great admiration for the intrepid aeronauts who navigated the balloon, and the ground staff who made the flight possible. Nevertheless, one is inclined to wonder whether, from a purely scientific point of view, the money would not have been better spent in sending up a large number of unmanned balloons. Practically all the apparatus was entirely automatic in operation and it was merely necessary for the crew to press a few switches. It might be rather difficult to operate the cosmic ray apparatus and ozone spectrographs in an unmanned balloon, but Regener has succeeded in doing this. The total weight to be carried up was enormously increased, both by the passengers themselves and by the air-tight stratostat with its air-conditioning apparatus. On the other hand, the popular appeal was far greater, which doubtless made it much easier to collect the necessary funds.

It is hoped that this flight will soon be repeated, as isolated observations become far more useful when substantiated by further data.

The report of the flight contains several very interesting photographs taken at the top of the flight. The most striking features in these pictures are the effects of erosion on the topography of South Dakota, and the sharpness of the top of the haze layer. Even more interesting are the photographs taken from an aeroplane at the exact moment of landing of the balloon.

Obituary Notices

Sir James Crichton-Browne, F.R.S.

SIR JAMES CRICHTON-BROWNE, who died on January 31 at the age of ninety-seven years, was born at Dumfries in 1840. His father was Dr. W.A.F. Browne, who became Commissioner on Lunacy for Scotland, and was at the time of his son's birth head of a famous private asylum in Dumfries—the Crichton Royal Institution. Crichton-Browne as a boy saw his father applying new methods to the treatment of the insane; they were treated as if they were rational human beings—they were employed according to their bent in the day-time, entertained in the evening and surrounded with the comforts of a home. His father believed in education—particularly of the young medical men who were to devote their lives to the care and treatment of insanity. It was in the late fifties of last century, when Crichton-Browne was a medical student in the University of Edinburgh, that Prof. Laycock of that University began to give lectures on the disordered psychology of the insane. In no other university or medical school in Great Britain was any attempt made to give systematic lectures on insanity. It was otherwise on the Continent.

It cannot, therefore, be a matter of surprise to find young Crichton-Browne, when he became a qualified medical man in 1861—he being then twenty-one years of age—resolving to do for the insane of England what his father had done for their unfortunate brethren in Scotland. In the year in which he qualified, he gave a paper to the Royal Medical Society of London on "The Clinical Teaching of Psychology". It is difficult to believe, as one reads that lecture now, that its mature thoughts are those of a young man of twenty-one. "There are," said he, "in the midst of your civilization, currents swift and relentless which are ever hurrying on countless contributions to that whirlpool in the vortex of which so many minds float wrecked". The full and rounded style with which he enlightened his listeners in those later days was already developed in 1861.

Newcastle-on-Tyne had discernment, and snapped up this young medical Scot and placed him in charge of its asylum, and the medical school of that city made him its lecturer on medical psychology. While still in his twenties (1866), he was made medical director of the West Riding Asylum at Wakefield. He brought enlightened and humane methods with him, and believing that the foundation of all progress in medicine depends on research, had a laboratory built and equipped in connexion with the asylum. A glance at the reports which were issued under his direction will show how well he planned. The most famous of all the researches done there was that which laid the fame of the late Sir David Ferrier (1843–1928). In the spring of 1873, Ferrier visited the West Riding Asylum, Ferrier being then thirty years of age. Crichton-Browne was his senior by three years, they had been at the University of Edinburgh together. A discussion sprang up on the experiments which Fritsch and Hitzig had done on the brains of dogs. The result was that Ferrier stayed on to repeat similar experiments and ultimately proceeded to apply faradic stimulation to the cortex of the brains of monkeys. These experiments laid the basis of our knowledge of localization of function in the cortex of the human brain. The incident is worthy of notice, for it illustrates the manner in which Crichton-Browne helped in the growth of scientific knowledge. There was no jealousy in his composition; he welcomed knowledge from any source, so long as it was real knowledge.

In 1875, Crichton-Browne left Wakefield to become a Lord Chancellor's visitor in lunacy. It was thus early that he became a feature of London social life: no gathering of medical or of scientific men seemed complete without him; he had a rare zest for public life. He was elected to the Royal Society in 1883, and at the time of his death he was senior fellow. In 1880, he became a member of the Royal Institution. James Dewar was then in the fourth year of his directorate; both men were steeped in the Edinburgh tradition. In 1889 he took over the honorary treasurership of the Institution, and held that office and all that it embraces until 1926. He was elected to the Athenæum Club in 1893. He took an active part in all medical societies which concern themselves with the life and disorders of the human brain.

It was during the later part of his treasurership at the Royal Institution that the writer of this note had the privilege of his friendship. One incident may be mentioned because of the light it throws on Crichton-Browne's character. Sir James Dewar was not always an easy colleague and was at times dictatorial—almost outrageously so. It so happened that towards the end of the Great War, Prof. H. H. Turner of Oxford was busy in the theatre of the Institution making ready for his Christmas lectures for children. Dewar entered to find Turner grouping a class of young children to represent the heavenly bodies and their movements. "What is this?" demanded Dewar. Turner explained. Dewar banned the scheme out of hand. Turner banged the lecture-room door and refused to return—on the eve of Christmas. It was then that Sir James Crichton-Browne appeared on the scene and in two days had peace restored and lectures assured. It was all accomplished by clear thinking, honest speaking and the pertinacity of a good heart. He combined in his person and in his mentality traits of both the centuries in which he had lived. He dressed his beard and his hair to the last in the fashion which prevailed when he was a young man in the late 'fifties; his oratory was of the kind beloved by the Gladstonians, but his attitude towards affairs was always modern.

Crichton-Browne loved his native town—Dumfries and all connected with it—especially Burns and Carlyle. His pen never wearied in their defence. Next to Dumfries came Edinburgh and its great men—especially Walter Scott. His interests were so diverse and so wide. Among his writers, Shakespeare stood highest, Scott next. His pen was always busy—always in search of his country's good. It is not necessary here to give a list of the non-professional books he wrote—from "The Nemesis of Froude" (1903) until the last of his reminiscences, which began to appear after his official retirement in 1922. The first volume of this series, "Victorian Jottings", appeared in 1926; the fifth, "The Doctors After-Thoughts", in 1932. Up to the last he and Lady Crichton-Browne went every year—spring and autumn—to breathe his native air at Crindau, Dumfries. It was during a visit to Crindau that death came to him. His brother, Balfour Browne, was the most successful parliamentary barrister of his time. Crichton-Browne himself had the makings of a great judge. Indeed he was a very great Victorian, the last of them. He was great not because of any contribution he himself made to medicine or science, but because he fostered the conditions which ensure the birth of knowledge in others. He was great both for what he did and for what he was. A. K.

Sir Thomas Stanton, K.C.M.G.

THE sudden death on January 25, at the age of sixty-two years, of Sir Thomas Stanton has come as a great shock to his many friends, both at home and abroad. Although Stanton, as director of Government Laboratories, Federated Malay States, and later, as chief medical adviser to the Colonial Office, occupied prominent positions throughout a large part of his life, he never sought publicity, and the public never fully appreciated the work which he had done on beriberi, on malaria and other diseases, or his work at the Colonial Office in reorganizing the Colonial Medical Service.

Stanton went to Malaya in 1907 and was soon engaged in the work with which, perhaps more than any other, his name will be permanently associated—the discovery of the cause of beriberi and of means for its prevention. At the beginning of this century, beriberi was certainly a medical puzzle. Its neuritis and paralysis were so similar to alcoholic and lead poisoning that few people doubted that beriberi was the result of the entry into the body of some poison. The late Dr. W. L. Braddon strongly maintained the hypothesis that the poison entered the system in white polished rice, and that it was absent from par-boiled and partly polished rice. But evidence that rice was not a factor seemed so conclusive from experiments conducted by the late Dr. E. A. O. Travers in two jails at Kuala Lumpur that in Manson's "Tropical Diseases", third edition (1903), it is stated: "This view has been disposed of effectively by experiments by Dr. Travers. This experiment was prolonged and scrupulously carried out." Braddon was not convinced, and a polemic ensued, as a result of which Dr. William Fletcher carried out an experiment in his hospital wards at Kuala Lumpur at the suggestion of his chief, Dr. Travers.

The question was far from being one of merely academic interest. There were hundreds of new cases of beriberi every year in Malaya. The tin mines suffered severely. Sometimes the disease attacked the jails so seriously that a sentence of six months' imprisonment threatened to be a sentence of death, or what might perhaps be regarded as worse, a life sentence of paralysis following beriberi. Fletcher set out to confirm Travers's view that rice played no part in causing beriberi. At the end of the experiment, he was convinced that rice was the cause of the disease. The next question was, How did the rice produce beriberi? It was at this point that Stanton and Fraser of the Institute for Medical Research entered on their work, which not only showed exactly how rice produced beriberi but also what rice produced beriberi and what rice did not produce the disease. They showed further that the disease was not, as Braddon maintained, caused by a poison in the rice, but was a deficiency disease caused by the removal of the pericarp in the polishing of the rice; and they proved that if a fowl were suffering from beriberi as a result of being fed on a polished rice, it could be rapidly cured by giving it the polishings. They found that unpolished rice never produced beriberi in fowls, and with the introduction of unpolished rice into the jails the disease rapidly disappeared. For a time it looked as if the amount of phosphorus pentoxide (P_2O_5) in rice could be taken as an indicator of the danger of beriberi developing, but further observations showed that this test could not be relied on.

The discovery was of great value in itself, and of vast economic importance to Malaya; so much so that had it stood alone it would have justified all the money that had been spent on the Institute for Medical Research from its foundation. But it had a still greater significance, for it suggested lines of research into other diseases, which in their turn proved to be deficiency diseases. To-day vitamins are a household word, and the accessory foodstuffs are studied in probably every country in the world. There can be few Governments which are not inquiring into and trying to improve the food of their nationals on the lines of the discovery made by Stanton and Fraser.

Space will not allow me to say much more on Stanton's work in Malaya. From 1911 until 1926 we were colleagues on the Malaria Advisory Board in the Federated Malay States, and Stanton's interest in this subject was shown not only by his valuable contributions to the discussions of the Board, but also by his researches into the morphology of the anopheline larvæ, which were of material assistance to the practical work of mosquito control and the prevention of malaria in Malaya.

May I conclude with a personal remark. No one could come into contact with Stanton without realizing that behind a quiet demeanour lay an active brain, carefully balancing the pros and cons of everything he discussed. What was perhaps not less important, he was a man who could be trusted; a scientific investigator of distinction and a great gentleman.

MALCOLM WATSON.

Dr. W. W. Vaughan

NEWS of the death on February 4 of Dr. W. W. Vaughan, as the result of an accident, will be received with deep regret by his many friends in scientific circles. A note in last week's issue of NATURE, p. 236, described the circumstances of the unfortunate fall, while visiting the Taj Mahal at Agra, which resulted in his death. When we went to press, it was reported by cable that his condition after the amputation of his leg was favourable, and it was hoped that he would make satisfactory progress toward the recovery of his normal good health. Those, however, who saw the serious nature of the accident at the time of its occurrence, when Dr. Vaughan had to lie in the open with a compound fracture for more than an hour before an ambulance could be found to move him to the Thomason Hospital, scarcely expected that he could recover, and their fears have been sadly confirmed by the fatal result.

Dr. Vaughan was one of the few headmasters of public schools who had been presidents of the Educational Science Section of the British Association; and he was distinguished among all of them who have occupied this office in the continued part he played in the work of the Association. It was while visiting India as a member of the delegation of the Association to the jubilee meeting of the Indian Science Congress Association that he met with the accident which has led to his death.

Dr. Vaughan was born in 1865 and was the son of Prof. H. H. Vaughan, regius professor of modern history in the University of Oxford. He was educated at Rugby School, New College, Oxford, and the University of Paris; and his main subjects were modern languages. In 1890 he became an assistant master at Clifton College, where he remained until 1904, when he was headmaster of Giggleswick School. From 1910 until 1921 he was master of Wellington College, and he then returned as headmaster to his old school, Rugby, where he remained until his retirement in 1931. He was president of the Modern Language Association in 1915, of the Incorporated Association of Headmasters in 1916, of the Science Masters' Association in 1919, and of the Education Section of the British Association in 1925. He served on the Consultative Committee of the Board of Education and on the Government committee appointed in 1916 under the chairmanship of Sir J. J. Thomson, on the position of natural science in the educational system of Great Britain. At the time of his death he was a member of the Council of the British Association and of the Advisory Committee on Education in the Colonies.

When Dr. Vaughan was president of the Science Masters' Association he dealt, in his presidential address, with the importance of science as part of a liberal education. He urged that the aim of scientific instruction should not be purely utilitarian but that of education as a whole—the liberation of man's soul. He referred to these objects again in his address to the Educational Science Section of the British Association. "We seem almost to have lost the will," he said, "to keep by education the pores of the soul and the mind ever open to the impressions of experience, to the stirrings of emotion, to the slow and enduring influence of the reason. We have too often pinned our faith on the production of dexterity, of mental facility, of almost thoughtless accuracy, and we have our reward in our educational looms being ill-adapted to the production of contentment and beauty and the power or the will to reason."

It was because Dr. Vaughan cherished these high educational ideals that his influence while a school master and since his retirement is appreciated by all who have come under it. By his lamented death, the educational interests of science have suffered a severe loss and his many scientific friends have to mourn the passing into silence of a helpful colleague.

WE regret to announce the following deaths:

Prof. H. H. Donaldson, for thirty-two years professor of neurology in the Wistar Institute of Anatomy and Biology, Philadelphia, known for his work on growth, particularly of the nervous system, on January 23, aged eighty years.

Mr. Alan E. Munby, architect of Clifton College Science School and other important science laboratories, on January 19, aged sixty-eight years.

Dr. Andrei Vassilievitch Martynov, professor in the Institute of Palæontology at Moscow, well known for his work on Trichoptera and fossil insects, on January 29, aged fifty-nine years.

Dr. F. G. Pease, of Mount Wilson Observatory, where he was responsible for the design of many large instruments, on February 7, aged fifty-seven years.

Prof. Herman Schlundt, chairman of the Department of Chemistry of the University of Missouri, known for his work on radioactivity, on December 30, aged sixty-eight years.

News and Views

The London School of Economics

IN a leading article on "Realistic Social Studies" in NATURE of January 22, incidental reference was made to the London School of Economics and it was stated "that responsible bodies which administer funds for research . . . have refused to renew temporary grants such as the Rockefeller subsidy to the London School". We are informed that the facts with regard to the Rockefeller Foundation are as follows: "During the past three years, four temporary grants from the Foundation to the School have been in force. Two of these for the purpose of site extension and library development still remain available; a third, providing funds for research, terminated in 1935 and was then renewed on a somewhat different basis for a five-year period; the fourth grant, providing facilities for post-graduate teaching and research, does not expire until the end of the current academic year. No formal application has yet been made by the School for the renewal of this grant: hence, no action has yet been taken. If the editorial of January 22 seems to imply that there has been any criticism offered or expressed by 'responsible bodies which administer funds for research' such an implication does not exist. In point of fact, no criticism as to the teaching and research in economics under way at the London School has ever been made on the part of any Foundations which have assisted it in the past and assist it now." The context of our comment made it clear that it referred to the grant which terminated in 1935, and that it had no relevance to any allocations for the purchase of books, for site extension or for post-graduate instruction. We were in receipt of full information concerning the "somewhat different basis" on which the grant was renewed. If, as we understand, the previous annual grant which terminated in 1935 was replaced by a reduced and tapering allocation, there seems little ground for objection to the statement published in our editorial. The main purpose of the article was to urge that the new Institute of Economic and Social Research should "tackle the fundamental problems arising from the way in which expanding technical resources react upon, and are used by, existing social institutions"; and the purpose will have been served if the article leads to the extension of social research in these directions. With Prof. Carr-Saunders as the new director of the School it may confidently be expected that increased encouragement will be given to such studies.

American Institute Awards

DR. W. CROCKER has been awarded the Gold Medal of the American Institute of the City of New York for "his contribution to knowledge of life processes in plants and for his unique leadership in the organization of plant research". Dr. Crocker was professor and director of research in plant physiology at the University of Chicago for many years. He organized and has directed the Boyce Thompson Institute for Plant Research from the time it was founded in 1921 to the present day. At the University of Chicago and the Boyce Thompson Institute for Plant Research he has acquired a reputation as an organizer and director of research. His method has been to bring together specialists in different fields of knowledge and to give these specialists an opportunity to work co-operatively on biological problems that have not yielded to attacks by individuals working single-handed. Dr. Crocker has also done noteworthy research. He was the first to show that ethylene gas in air in amounts far too small to be detected by any known chemical means causes profound reactions in plants. He proved that ethylene 'puts plants to sleep'. He has shown how certain seeds that remain dormant for many years may be induced to grow if given proper treatments. Low temperatures, chemicals, light and other environmental agencies have been used to break these long rest periods. His work on the physiology of dormancy in seeds has contributed to fundamental knowledge of life processes. The Gold Medal of the American Institute may be awarded either to organizations or to individuals.

WALDEMAR KAEMPFFERT, science editor of the *New York Times*, and Dr. Raymond L. Ditmars, curator of reptiles and mammals of the New York Zoological Park, have been awarded fellowships of the American Institute for their contributions to science. Mr. Waldemar Kaempffert was awarded the fellowship "for his scholarly interpretation of scientific advances, for his editorial wisdom, for his adroit cultivation of the public mind toward a rational outlook and for his leadership in enforcing their social responsibilities upon scientists". Mr. Kaempffert, who is president of the National Association of Science Writers, has for many years been a leader in the promotion and maintenance of the high standards of science reporting in the United States. He took up his duties as science editor of the *New York Times* in 1927, leaving in 1928 to become the first director of the Museum of Science and Industry in Chicago. He is responsible for the real establishment of that great institution for the interpretation of science to the public. Mr. Kaempffert returned to the *New York Times* in 1931, where his weekly columns on the latest developments of science have become a source of invaluable information to thousands of readers not only on the facts of science but also on its philosophy.

DR. RAYMOND L. DITMARS has received the American Institute fellowship "for his thirty-seven years of distinguished service in the care, understanding and interpretation of the reptile world and for his inspiring of youthful spirits with the zeal of the naturalist". Dr. Ditmars is the author of many fascinating volumes on his work with snakes, including "The Making of a Scientist", "The Thrills of a Naturalist's Quest", "Snakes of the World" and "The Forest of Adventure", which latter presents his subject especially for boys and girls. At his laboratory in the New York Zoological Park, Dr. Ditmars is engaged in biochemical research on the subject of snake poisons as a useful substance for the treatment of certain human ailments, including hæmophilia, the reduction of pain, and epilepsy. In announcing these fellowships, Dr. Gerald Wendt, director of the American Institute, explained that they were awarded each year by the Institute to "persons who have done outstanding work in the interpretation of scientific, engineering or industrial work, which promotes with effectiveness the knowledge and general understanding of these arts and sciences. The recognition of these interpreters of science is an important element in the Institute's programme, which has as its primary purpose the integration of scientific advances with the social structure."

The Soviet North Polar Station

DURING the last two months, the Soviet observatory placed on a floe near the North Pole in May 1937 has been drifting rapidly southward in the East Greenland current. Fortunately for the safety of Papanin and his three companions, the drift cleared the north-east corner of Greenland and the floe appears to have kept to the outside of the stream of ice down the coast On February 3, the station was reported to be in lat. 74° 8′ N., long. 16° 24′ W., which was within about eighty miles of the Norwegian observatory o Myggbukten at the mouth of Franz Josef Fjord in East Greenland. It is reported that although this station is not functioning, it shelters a wintering party of four men provided with dog teams. To try to reach the shore, however, over the drifting and grinding pack would be difficult and hazardous The floe on which the Soviet party is living has split; the men have lost some of their equipment and are now on a small floe, but they have their tents, instruments, three months' stores and sledges.

RELIEF for the expedition is being hurried forward but will be impeded by the winter darkness and the difficulty of finding an adequate landing place for aeroplanes. *The Times* reports that the small wooden survey vessel *Murmanets* is near Jan Mayen, a distance of less than two hundred miles, and that the Arctic ship *Taimyr* has left Murmansk with aeroplanes and dog teams. Cinematograph equipment is being taken by the *Taimyr* and it is hoped to film the voyage of the vessel, the North Polar station, the removal of Papanin and his companions from the ice-floe and their return home. As the work will have to be done in the darkness of the Polar night, portable lighting equipment to be operated by current from the *Taimyr* is being taken. In th event of the vessel being unable to approach clos enough to the ice-floe, a small portable generator and magnesium flares will be used. The *Taimyr* ha been delayed by heavy weather and the mor powerful *Murman* sailed from Murmansk on February 6. The icebreaker *Yermak*, with aeroplanes, was to leave Leningrad on February 8, but has a long journey ahead of her. Aeroplanes are also leaving Green Harbour, Spitsbergen. Prof. O. Schmidt i directing the relief operations. Papanin's messag that wireless communication may be interrupted bu that there is no immediate danger expresses th daring of these adventurous men. The Norwegian and Danish authorities have offered to assist in th rescue work.

Colour Television at the Dominion Theatre, London

ON February 4, a surprise item was introduced into the regular programme of the Dominion Pictur Theatre, London. At 8 p.m. an experimental demon stration of Baird colour television was effected fo the first time in public. The sending station was the South Tower of the Crystal Palace, the wave-length employed being 8·3 metres. The quality of the pictures was naturally much inferior to those with which the present-day viewer is familiar: only 120 scanning lines being used as compared with the 400 lines now employed by the British Broadcasting Corporation. The projected picture was twelve feet by nine feet and could be clearly seen by everyone in this large theatre. It was illuminated by a high-intensity arc lamp. The programme included the transmission of fashion plates of ladies hats; the various coloured flowers were quite brilliant and the gaily and variegated headgear sometimes used by officers abroad came out very distinctly. A coloured cartoon of Popeye the Sailor caused much amusement. Colour television is still in the early stages of development, but the transmission was very successful and the unexpected show was well received by the spectators.

The present apparatus used by Baird Television transmits a 120-line picture, the scanning at both transmitter and receiver being by mechanical means. The transmitter consists of a mirror drum with twenty mirrors inclined at different angles revolving at 6,000 r.p.m. These mirrors reflect the scene to be transmitted through a lens, causing an image to be formed on a rotating disk with twelve concentric slots at different distances from its periphery. By this means the field given by the 20-line drum is interlaced six times to give a 120-line picture repeated twice for each revolution of the disk. Each of the slots is covered with a light filter, blue-green and red being used alternately, the effect of this being to transmit alternate lines of the picture corresponding to a blue-green image and a red image. At the receiving station a similar device is employed, the rotating drum in this case being much larger (12 in. in diameter in place of the 8 in. at the transmitter). Light from a high intensity arc lamp is concentrated on the moving aperture in the disk and yields sufficient light to fill a screen 12 ft. × 9 ft.

Archæological Expedition to Syria

Sir Leonard and Lady Woolley, it is announced, are leaving England for Syria, where the British Museum Expedition under Sir Leonard's direction will resume excavations immediately at Tell Atchana in the Amk plain on the Orontes, North Syria. This site, as has been shown by the previous seasons' excavations, has surpassed anticipation in its importance for the cultural relations of Asia and the eastern Mediterranean at an early date. The results which have been obtained already, as has recently been demonstrated by Sir Arthur Evans, when correlated with the information now accruing from the excavations of French archæologists at the Syrian site of Ras Shamra, have already thrown light on chronological and other problems of the Minoan civilization of Crete, as well as indicated the extent of Cretan influence on Asianic culture. The work of the British Museum Expedition in the coming season will be devoted mainly to the further exploration and clearing of the palace, of which, as was pointed out by Sir Leonard Woolley in his recent lecture before the Royal Institution (see Nature, January 29, p. 194), the architecture both in material and in style is as essentially Cretan as the painted pottery discovered on this site. It is hoped that additions to knowledge of political and social conditions of the time may accrue from further discoveries of the cuneiform tablets, from which it has already been established that the building is a royal palace dating to about 1600 B.C. Sir Leonard Woolley will be accompanied by Mr. P. W. Murray-Threepland, who will again act as his assistant, and by Mr. Ralph Lavers, acting as architect of the expedition, who has had previous experience of archæological investigation at Tell el-Amarna in Egypt and in Crete.

Dynamic Ecology of Sand Dunes

At the Friday evening discourse at the Royal Institution on February 4, Prof. E. J. Salisbury discussed "Plants of the Sand Dunes and Why They Grow There". Sand dunes are a unique type of habitat. They depend on plants for their development. They show such rapid changes that the dynamic character of communities of plants is here forced upon our notice. Moreover, because a sequence in space corresponds to the sequence of development in time, the nature of these changes can be ascertained with certainty. The pioneer plants are rapidly growing grasses equipped with leaves which are so constructed that they automatically adjust their rate of water loss to the water income. Further, these grasses can endure burial by sand and are indeed stimulated thereby to grow through to the new surface. All these features enable them to endure the desert-like conditions and mobility of their rooting medium. Although the water content of young dunes is less than four per cent, it is maintained at a comparatively constant though low level owing to the occurrence in sunny weather of conditions that promote internal deposition of dew within the dunes. Sand dunes thus illustrate in a striking manner the dynamic character of vegetation and the fallacy of the widespread belief that to preserve a natural area all that is necessary is to leave it alone.

Dublin Zoo and Bird Sanctuary

At the annual meeting of the Royal Zoological Society of Ireland, held at Dublin on January 26, Lord HolmPatrick was re-elected president, Dr. J. Agar Matson honorary secretary, Mr. Cecil Pim honorary treasurer. It was announced that Dr. B. B. Farrer, superintendent and secretary of Dublin Zoo for the past twenty-six years, is retiring. Dr. Matson reported that during the year 1937 there was an increased attendance at the Zoo of 152,173 visitors as against 151,109 in 1936, receipts having increased from £3,561 to £3,661. Membership increased by 54. The Government's grant of £1,000 was continued and various improvements and works are being carried out, the new bear enclosure now nearing completion. More than £520 was spent purchasing and transporting animals like penguins, sea-lion, wolves, wallabies and laughing jackass; but owing to various restrictions some valuable animals offered could not be accepted. The meeting was followed by a lecture by Father P. J. Kennedy, a well-known local ornithologist, on the birds of Phœnix Park. Father Kennedy gave a detailed history of the formation of the Park until it was turned into a bird sanctuary in 1937, its trees, shrubs, lakes and ponds being so valuable. The birds he then discussed were the 83 species which have been observed in the Park, and included grey crow, rook, jackdaw, magpie, jay, starling, greenfinch, goldfinch (which he said is increasing), chaffinch, bullfinch, linnet, crossbill, yellow-hammer, skylark, pied wagtail, tree-creeper, black-cap and spotted fly-catcher.

The Maidenhair Tree

THE origin of the curious generic name, *Ginkgo biloba*, of this tree is very fully discussed, with reference to original Chinese and Japanese descriptions, by Prof. A. C. Moule in *T'Oung Pao*, 23, published by the firm of E. J. Brill, Leyden. The name seems to be due to Engelbert Kaempfer, a German naturalist (1651–1716) who was in Japan apparently about 1690–2. The Kaempfer MSS. are stated by Larousse to be preserved in the Museum of Botany at Leyden where, however, search has failed to find them; Prof. Moule, however, through Sir Albert Seward, has traced the original entries of Kaempfer in his manuscripts in the British Museum. These seem to make it clear that when Kaempfer, some eighteen years later, published the names from his original descriptions, he deciphered incorrectly an original manuscript entry of Sankyo in the form of *Ginkgo*, where it is difficult to decide whether the 'g' is a slip in transcription or a misprint that has been overlooked. Thus "this strange word, which is unpronounceable and probably ought never to have existed, has been for nearly two centuries and, I suppose, will always be the generic name of this beautiful and interesting tree". There is a very full discussion of the numerous Chinese names of this tree which are all either descriptive names of two or more words or are frankly borrowed from other trees, suggesting that the tree was not known in northern China during the centuries when the Chinese classical civilization and language were being formed. This may confirm the view of F. N. Meyer and others that the tree is indigenous in the forests of Chê-Chiang, but in favour of the other view that it survives only in cultivation is the fact that no large speqimens have been reported from forests. There is an interesting discussion of its fire-resisting qualities, which were exemplified by the recovery of many trees in Tokyo after the big fire that followed the earthquake in 1923; popular testimony thus made a huge *Ginkgo* tree largely responsible for the survival of the great temple of Kwannon at Asakasa; it was believed that the tree literally rained moisture on the roof, and also protected it against burning fragments carried in the wind.

Health Committee of the League of Nations

AT the twenty-fifth session of the Health Committe of the League of Nations, April 26–May 1 (G. Alle and Unwin, League of Nations Department 40 Museum St., London, W.C.1: Report to th Council on the Work of the 25th Session o the Health Committee, 1*s*.) the next three-yea programme was discussed and approved. Amon the permanent activities of the Committee, it work on biological standards is far from bein completed. New therapeutic agents gain acceptan with the advance of science and require assay i terms of some common standard, and other standard already adopted are either open to improvement or being composite, are liable to be replaced sooner o later by the active substance in pure form, apar from the possibility of physical or chemical method replacing the biological method. Forty-one countrie have adopted or are about to adopt the internationa standards recommended by the Permanent Commission on Biological Standards, and thirty-on Governments have established or are about t establish national centres, thus simplifying the tas of the central institutes at Copenhagen and Hampstead. For drugs like digitalis, pituitary extract an arsphenamine, no insuperable difficulties are anticipated in preparing national standards, but it is expected that for serological standards the Copenhage Institute will have to continue to supply internationa standard sera to most of the national centres. Th standardization of anti-anthrax serum, examined i 1925, requires further investigation in collaboratio with the Institute at Budapest and Bucharest Further study of the standardization of anti-swine-erysipelas serum is also necessary as well as consideration of changes in the international standard for tuberculin and staphylococcus anti-toxin. The standardization of anti-snake venom sera, pharmacological standards, as well as those for vitamins and sex hormones, also fall within the next three-yea programme of the Commission. Other matters i the programme of the Committee are leprosy, rural hygiene, housing, physical education, nutrition an opium and other dangerous drugs.

Dietetics and Social Problems

THE problem to what extent a wise social policy, taking into account modern scientific developments in the field of nutrition, can help to raise the standard of living in certain countries, or for certain categorie of population, which at present suffer from undernourishment or malnutrition, is being investigated by the International Labour Office, assisted by a Committee of Experts which met at Geneva on April 9–10, under the chairmanship of Mr. Bramsnaes. This committee discussed the efforts of the International Labour Office to demonstrate the progres of dietetic science and its importance in regard t social questions. Special stress was laid on th necessity of distinguishing between the physiological, health and social aspects of the problem, and it wa agreed that the studies should be studied simultaneously in various countries according to a uniform plan which would assist international co-ordination of comparative results. The projected investigations are aimed at determining the relation between nutritional requirements and different occupations, the economic and social effects of different policies of improving the standard of nutrition of workers and their families, and at defining the principles on which the regulation of wages, where it exists, is based and methods of fixing benefits under social insurance or assistance schemes. Other studies will deal with the nutrition of apprentices and young persons and of the unemployed, etc.

Rural Electrification

AT the present time many people are interested in the supply of electricity for thinly populated districts, but they are only beginning to realize that it is a very safe commercial venture. There is a great demand for an electric supply at a reasonable cost and the expense of advertising by demonstration vans, etc., is not great. In a paper on this subject read by J. S. Pickles to the Institution of Electrical Engineers on December 2 it is pointed out that in many countries abroad the public supply of electricity is regarded as a necessity. As a practical example of what can be done by borough councils, he gives a description of the Dumfries scheme, which covers the whole of a geographical county of 1,070 square miles in area. With the exception of only one town, no electrical development had previously taken place in the supply area. The scheme was begun six years ago, the electric supply being purchased by the borough from the Central Electricity Board. The policy adopted aimed at providing supply to every consumer without asking him to make a contribution towards the capital cost, no matter what was the length of his necessary service main. Neither was he asked to pay any guaranteed minimum revenue. The adopted scheme provided for the immediate erection of a comprehensive system of overhead wires with the necessary transformers, etc., capable of giving a supply practically to all prospective consumers within the area. It was recognized that the expenditure of large capital sums in the early years would lead to commercial deficits unless the development amongst consumers was very rapid.

THERE is an assisted wiring scheme extending over five years for the consumer and no initial payments of any kind are required. A two-part tariff is usually adopted. The consumer pays ¾*d*. per unit for running costs and 5 shillings per room per quarter, no charge being made for sculleries, bath rooms, box-rooms, etc., and 20 is the maximum number of rooms for which a charge is made. A radiator can be hired for 1*s*. 6*d*. per quarter and a wash boiler for 2*s*. 6*d*. A two-part tariff meter has been adopted, which collects both the fixed and the running charges. Very few of the consumers go for long holidays, and so the supply is never cut off for long periods. As many of the consumers have 'all-mains' wireless sets they never allow their supply to be cut off for long. During the first five years of working the scheme there have been small deficits in the year's working, but it is estimated that from the sixth year onwards there will be a profit. Doubtless later on there will be a reduction in the consumer's charges, as the demand seems constantly increasing.

The *Modern Quarterly*

WE welcome the first number of the *Modern Quarterly* (offices: 2 Parton Street, London, W.C.1), because throughout it proclaims the supreme importance and the social function of science in the contemporary world. But we must add a qualifying regret that it appears both from its contents and the personnel of its editorial council to be inclined to identify the progress of science with one form of the organization of society and especially of industry. This must prejudice many readers against the suggestive ideas and generally high aims of the promotors. Must we accept Marx, Lenin and Russia, it will be asked, as the gospel and best exemplification of science in society? Are not the more liberal, though more slowly moving societies, like our own, perhaps doing the work of human evolution even more effectively in the long run, certainly without the bitterness and the bloodshed of the revolutionary method? But these are large questions impossible to discuss in a note. Of the articles in this number, two should be especially mentioned: the first, by Prof. H. Levy, acutely criticizing the mechanistic explanation of the universe, and the fourth, by Dr. Joseph Needham (the bulk of his Herbert Spencer Lecture at Oxford), in which he attempts a revaluation of Spencer's presentation of the idea of progress. This is the most valuable part of this first number and deserves careful study, none the less because it contains conspicuous examples of the communistic doctrines referred to above. Mr. Max Black has an article carefully considering and criticizing the doctrines of Wittgenstein and the logical Positivists. It is rather a remarkable feat to be able to write a complete, though short, account of "The Evolution of Positivism" (including the nineteenth century) without even mentioning the man who first systematized that way of thinking and gave it its name.

Earthquake in the East Indies

ONE of the greatest earthquakes for several months past occurred on February 1. The first movements were recorded at Kew at 7 h. 19 m. 52 s., p.m., and the largest oscillation about three-quarters of an hour later. According to Mr. J. J. Shaw, it was a very deep-seated earthquake. The records at Kew and Bombay show that the distances of the origin from these two places are respectively 8,250 and 4,250 miles. Thus, the earthquake occurred in the Banda Sea in about lat. 5° S., long. 130° E., at 7·5 p.m., G.M.T. (February 2, 1.45 a.m., local time). Three earthquakes, with a focal depth of about 260 miles, occurred close to the spot indicated (in lat. 5·5° S., 130° E.) on May 10, 1920, and March 23 and 24, 1921; while two others, with the same focal depth, originated in a centre lying five degrees to the east on October 10, 1921, and February 19, 1923.

Both foci lie close to the great arc of Sumatra, Java, Sumbawa, Flores, etc., along which many other earthquake centres, deep-seated and otherwise, are clustered.

Association for Physical Medicine

THIS society was inaugurated on January 27 at 56 Russell Street, W.C.1, with Dr. P. Dalton in the chair. The aims of the Society are: (1) To co-ordinate the various branches of physical medicine under one control; (2) to co-operate with manufacturers in the production of suitable appliances for medical and surgical use, and to prevent their sale to unsuitable persons; (3) to secure a national register of those practising the science and to affiliate all appropriate bodies; (4) to institute a chair of physical medicine in one or more of the universities and to establish a post-graduate school; (5) to establish contact with the general practitioner and to keep him informed of the changes in the subject; (6) to establish a technical board to act in an advisory capacity.

Announcements

ON February 12, two men of science of international reputation celebrate their birthdays. Prof. W. B. Scott, emeritus professor of palæontology in Princeton University, is eighty years of age; and Prof. Otto Pettersson, the Swedish chemist and oceanographer, is ninety years on that date. They may be assured that they have the congratulations and best wishes of scientific workers everywhere.

THE fifteenth Duddell Medal of the Physical Society has been awarded to Prof. H. Geiger, professor of physics in the University of Tubingen.

THE triennial award of the Coopers Hill War Memorial Prize and Medal, which fell in 1937 to the Institution of Electrical Engineers, has been made to Dr. T. E. Allibone for his paper on "The Mechanism of the Long Spark".

THE Council of the Institution of Civil Engineers has made the first award of the James Alfred Ewing Medal to Mr. Charles Samuel Franklin. This medal was founded in 1936 in memory of Sir Alfred Ewing, and is awarded, irrespective of membership of the Institution, for specially meritorious contributions to the science of engineering in the field of research.

PROF. W. P. JORISSEN, of the University of Leyden, will deliver a lecture entitled "Reactions in Gaseous and Solid Mixtures", in the Chemistry Lecture Theatre of the Imperial College of Science and Technology, on February 21, at 5.15 p.m. Admission to the lecture is free.

FIVE lectures on science and industry have been arranged by the Association of Scientific Workers, to be given in the Chemistry Theatre, University College, London. The lectures are as follows: February 16, Sir Richard Gregory on "Science and Industry"; February 24, Sir John Russell on "The Application of Science to Food Production"; March 2, Major F. A. Freeth on "Science and the Chemical Industry"; March 9, Dr. E. A. Rudge on "Training for Industry"; March 17, Dr. F. S. Sinnatt on "The Fuel Research Survey". The lectures will be given at 8.15 p.m. Tickets are obtainable from the Secretary, Association of Scientific Workers, 28 Hogarth Road, London, S.W.5, free to members and 1*s*. 6*d*. to non-members for the series, or 6*d*. for a single lecture.

AT the annual general meeting of the National Institute of Sciences of India, held on January 8, the following were elected officers: *President*, Prof. M. N. Saha; *Vice-Presidents*, Prof. S. S. Bhatnagar and Brevet-Colonel R. N. Chopra; *Treasurer*, Dr. B. S. Guha; *Foreign Secretary*, Prof. B. Sahni; *Secretaries*, Prof. S. P. Agharkar and Dr. A. M. Heron.

THE Medical Research Council has been entrusted with an annuity of £350 for a period of twenty-five years, provided by the late Mr. Eugen M. Schlesinger and by Mrs. Schlesinger to establish a memorial to their daughter in the form of a Kathleen Schlesinger Research Fellowship. This is to be given for investigations on the subject of cysts of the brain or allied conditions, and will ordinarily be tenable at the National Hospital for Diseases of the Nervous System, Queen Square, London, for periods of from one to three years. Awards will be made by the Council with the assistance of a special advisory committee appointed in terms of the trust deed.

DR. EUGEN FISCHER, professor of anthropology in the University of Berlin, and Dr. Hermann Lautensach, professor of geography at Greifswald, have been nominated for honorary doctorates of the University of Coimbra.

THE annual congress of the German Society of Balneology and Climatology will be held at Kiel on February 24–27. Further information can be obtained from Dr. Pfleiderer, Tirpitzstrasse 12, Kiel.

THE fortieth Congress of the German Zoological Society will be held at Giessen on July 4–6, 1938. Further information can be obtained from the Secretary of the Society, Invalidenstrasse 43, Berlin, N.4.

DR. G. D. BHALERAO, helminthologist of the Imperial Veterinary Research Institute, Muktesar-Kumaun, India, is to prepare a volume in the "Fauna of British India" on Trematoda.

IN the article entitled "Museum Study of Man and his Work" in NATURE of December 25 (p. 1108), reference is made to the Colonial Institute at Haarlem. This is incorrect; the Colonial Institute is at Amsterdam.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

Notes on points in some of this week's letters appear on p. 291.

Correspondents are invited to attach similar summaries to their communications.

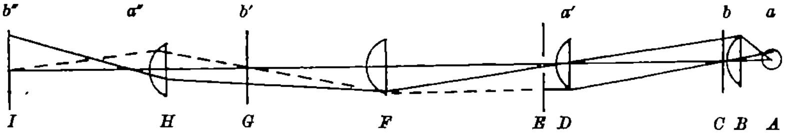
Direct Photography of Ultracentrifuge Sedimentation Curves

Several good methods now exist for observing the sedimentation boundary in the ultracentrifuge. That described here should, however, be useful because it is the least laborious way of producing a 'sedimentation diagram' (that is, a curve relating concentration gradient to distance from the axis of rotation). It is probably not so accurate as the 'scale' method[1], though this question seems worth investigating; but certainly the accuracy is sufficient for a great many purposes.

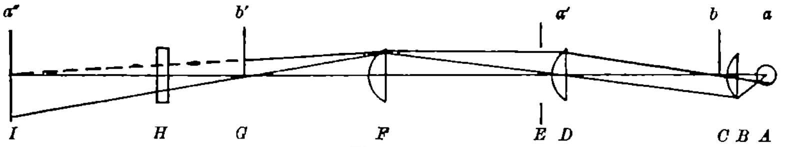
The method is based on the *Schlieren* principle as adapted to the ultracentrifuge by Tiselius *et al.*[2]. Added to this is a modified form of Thovert's principle[3] involving a diagonal edge and a cylindrical lens. The limitation which makes Thovert's own arrangement unsuited to the ultracentrifuge (cf. Lamm[1]) has been circumvented in that the optical path through the centrifuge cell can be made as narrow as desired without restricting the width of the photograph.

The optical path is shown in Fig. 1. Conjugate foci are marked *a*, *a′*, *a″* or *b*, *b′*, *b″*. *A* is the light-source, *B* a condensing lens which focuses a large image of *A* on the centrifuge cell *E*. *C* is a rectangular stop, the upper edge of which is smooth and straight. It is focused by the spherical lenses *D* and *F* on a similar stop *G*, which is inclined at an angle to *C*. *H* is a cylindrical lens with vertical axis. Seen in plan, it focuses *G* on the photographic plate *I*. In elevation *H* has no effect, but *F* focuses *E* on *I*.

From *A* to *G* the arrangement is identical with an ordinary *Schlieren* arrangement, except that *G* happens to be farther from *F* than is usual. At *G* the diagonal edge causes light which is deviated upwards to be obstructed at one side but not at the other, and the cutting-off point is shifted sideways proportionately to the upward deviation. The cylindrical lens *H* focuses the sideways shift on the plate while the cell is still focused vertically. The dividing line between light and darkness therefore takes the form of the required sedimentation diagram since the upward deviation at *G* (and therefore the sideways shift at *I*) is proportional to the gradient of refractive index and concentration. If θ is the angle at any particular height in the cell made by the edge *G* with the vertical, the sideways shift caused by unit concentration gradient varies as $\tan\theta$. Hence the sensitivity may be varied between zero and infinity by rotating the edge.



Plan



Elevation.

Fig. 1.

The compression in the cell introduces a linear term in the gradient of refractive index, which is equivalent to the introduction of a horizontal cylindrical lens. This may be compensated by introducing a cylindrical lens of opposite sign at *D*, but in practice it is sufficient to move the stop *C* or the spherical lens *D* along the optical axis. There is also some irregular curvature due to bulging of the quartz plates in the cell, which cannot be compensated automatically and must be allowed for if high sensitivities are used.

Introduction of another vertical cylindrical lens between *E* and *F* improves the illumination, but is not essential.

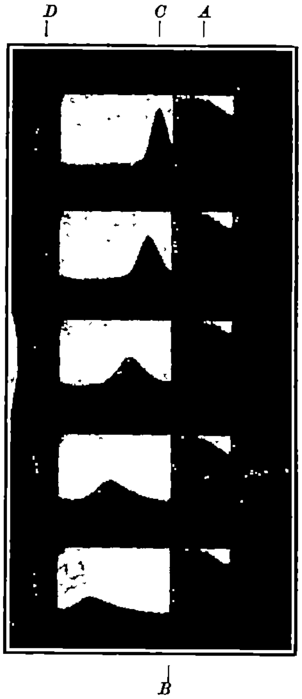


Fig. 2.

Sedimentation of lysozyme. *A*, paraffin; *B*, meniscus; *C*, sedimentation boundary; *D*, index'. Force, 300,000 times gravity; exposure interval, half an hour; concentration, 0·6 per cent; cell thickness, 6 mm. Specimen provided by Dr. E. R. H. Roberts.

Fig. 2 shows photographs of the sedimentation of lysozyme ($s = 2 \times 10^{-13}$) taken by this method. The edge of the curve is not quite sharp. Simple theory, verified by experiment, shows that the sharpness increases with increasing brightness of the source or time of exposure, and decreases with increasing sensitivity. The source used at present is a Pointolite, without colour-filter, and there is slight chromatic aberration due to dispersion by the protein and to residual error in the corrected lenses *D* and *E*. For these reasons it is preferable to use intense monochromatic light, from a filtered high-pressure mercury arc.

In interpreting the photographs it is sufficient for many purposes to note the general shape of the curves and to measure the positions of the maxima to the nearest 50 μ with a rough comparator. For the highest accuracy the sideways shift is best measured with a photo-electric comparator and plotted out after subtracting the base-line obtained from a control run. This is as laborious as the scale method and is seldom worth while. If the concentration of sedimenting protein is required, the curves must be integrated, and the particular arrangement of black and white should be ideally suited to photo-electric integration. This has not yet been attempted.

No exact comparison of accuracy with that of the scale method has yet been made. It is easy to obtain a sideways shift twenty times as great as the upward one given by the most sensitive setting of the scale method, and to measure it photo-electrically to the nearest 20 μ with high reproducibility, but there are many possible systematic errors analogous to those which have been studied in the scale method (Lamm[1]) and of which a similar study will have to be undertaken.

Electron-Multiplier as an Electron-Counting Device

MY efforts aiming at improving the electron-counting devices already known and extending their range in the visible part of the spectrum when used for counting photons have led to the application of the so-called electron-multiplier, based on the secondary emission principle. Recent experiments which I have carried out have shown its usefulness in the detection of individual electrons. The application of the method described here is easy and gives reliable and reproducible data.

An electron-multiplier tube with cæsium electrodes has some inherent disturbing effects that hinder the direct application of this tube as a counting device. Among them are the thermal emission of the cæsium surfaces and the leakage current.

The thermal emission, calculated according to Richardson's law, is 10^{10} electrons/cm.^{2}/sec. at room temperature, taking $\varphi = 0{\cdot}75$ volt for the work function and $A = 9{\cdot}8 \times 10^{-2}$ amp./cm.^{2} degr.^{2} for the first Richardson constant. (The electrons emitted by the first electrode give rise to a multiplication in n stages, the electrons of the ith electrode to that in the $n-i+1$ stages and these together create a basic current in the collector corresponding to the zero illumination. For example, this current has been found in one case to be 17×10^{-6} amp. at room temperature, in accordance with the value given above.) This current determines the lowest limit of the sensitivity of the multiplier and seems to prevent the use of the multiplier as an electron-counting device. It is easy to see that cooling in liquid air practically annihilates the thermal emission. Using the same data as above, Richardson's law gives immediately the number of electrons/cm.^{2}/sec.:

$$n = 0{\cdot}35 \text{ at } 150^\circ \text{ K. and } n = 6{\cdot}7 \times 10^{-10} \text{ at } 120^\circ \text{ K.}$$
